Once the atlas is assembled it is considered immutable for any subject to be registered. The following step is to displace the atlas image on top of any cardiac CT image that is on the proper fat range and that has the retrosternal area visible and, to compute a similarity score associated to every possible position of the atlas. A weighted mutual information (WMI), as shown in Equation (1), was chosen for computing the similarity score. Hence, we are autonomously recognizing the pattern of the retrosternal area on an arbitrary patient in order to suppose its location. After assuming its location on the basis of the WMI score, a heuristical confirmation method was applied to reinforce the chosen position. Once the position is set, all the retrosternal areas of the patients being registered are aligned, based on the recognized landmark, to a common

position. It is important to emphasize that this registration step is required to be done on a single slice of each patient; and the same transformation is applied to the remaining.

$$WMI_{y,x}(F,M,g) = \left(\sum_{f\in F}\sum_{m\in M}\frac{1}{|f-m|+1}\rho_{FM}(f,m)\log_g\frac{\rho_{FM}(f,m)}{\rho_F(f)\rho_M(m)}\right) \quad (1)$$

The variable F represents the fixed slice, M represents the moving atlas and g stands for the base of the logarithm. In the traditional formulation of the mutual information, each event or object specified by (f,m) is weighted by the corresponding joint probability $\rho_{FM}(f,m)$. This assumes that all objects or events are equivalent apart from their probability of occurrence. However, in some applications, it may be the case that certain objects or events are more significant than others, or that certain types of associations are more semantically important than others. Thus, we combined the mean difference measure with the mutual information, originating a weighted measure by the difference mutual information measure previously shown in Equation (1).

Classification

The classified segmentation can be viewed as a simple iteration through a set of pixels of an image (or voxels of a 3D model) where a set of features (i.e., characteristics) related to the iterated pixel, voxel, or surrounding area is extracted. The set of features is commonly called the features vector. The vectors are often united to compose a dataset that is provided as input to a classification algorithm.

In order to generate a concise predictive model we need to provide reliable data for training the classification algorithm. Therefore, two specialists, one being a physician and the other being a computer scientist, have manually segmented the epicardial and mediastinal adipose tissues of 20 patients (10 male and 10 female). Thus, our ground truth contains approximately 900 manually segmented cardiac CT images. It is important to highlight that prior to the manual segmentation, the images were already registered by our methodology. The created ground truth is available at [27]. The black value (0) represents the background and these pixels are excluded from the feature extraction and from the statistics. All other pixel values represent the selected cardiac fat range: (-200,-30) HU.

Similarly to the approach of Rikxoort *et al.* [28] for the classified segmentation of the liver, we have selected features: the pixel grey level and the position x, y and z, where z is the index of the slice. Besides, we have also selected the x and y positions relative to the center of gravity of the image and texture-based features from a neighborhood of variable size that encapsulates the iterated pixel at its center, i.e., a surrounding window of pixel values. Some features were selected on a theoretical basis and extracted from this neighborhood, such as: (1) a simple arithmetic mean of the grey levels, (2) moments of the co-occurrence matrix, (3) geometric moments, (4) run percentage, (5) grey level non-uniformity and (6) a 1D Gaussian-weighted mean of the grey values [24]. There are three possible classes for a pixel in our problem, namely, (1) epicardial fat, (2) mediastinal fat or (3) pixel of the pericardium (or unknown). These classes were evaluated separately and, therefore, the problem was reduced to a binary classification (true or false) for each one of these three possible classes [24]. If an incoming pixel is classified as epicardial and mediastinal, the result is a hybrid class of both. If it is classified as pericardium and has no current label, the result is also the same hybrid (further represented in yellow in Figure 3).

Results

Following feature selection, some classifiers were selected for a first evaluation of the convergence speed. For this trial, we extracted the features from the slices of just one single patient (approximately 13 107 200 features vectors) in order to speed up the analysis. All the classification and clustering algorithms in Weka [30] were selected for evaluation, some of these algorithms are, namely, the Support Vector Machine (SVM), Sequential Minimal Optimization (SMO), Naïve Bayes, Radial Basis Function (RBF) Network, Random Trees, C4.5 (or J48), Primal Estimated Sub-Gradient Solver for SVM (SPegasos), REPTree, k-Nearest Neighboor (kNN), Multilayer Perceptron and others. The parameters used by the evaluated classifiers were based on their standards with a small tweaking in some cases and the best result was selected. The algorithms present in Table 1 were the only ones that converged within an interval of 200 seconds (constructing and evaluating the predictive model). The values stand for mean accuracies and times of the three possible classes on a neighborhood size of 5x5 pixels.

Table 1 – Accuracies and convergence time on a single patient

Algorithm	Accuracy	Time (s)	Acc/Time
J48Graft	99.0%	132.86	0.75
RandomForest	98.9%	112.57	0.88
REPTree	98.9%	10.34	9.56
J48	98.9%	151.23	0.65
SimpleCart	98.9%	108.78	0.91
SMO	98.3%	58.66	1.68
RandomTree	97.5%	8.0	12.19
RBFNetwork	96.8%	3.48	27.82
SPegasos	96.8%	15.77	6.14
DecisionStump	96.8%	52.34	1.85
HyperPipes	94.8%	0.04	2370.0
NaiveBayes	86.0%	55.48	1.55

At first glance, the REPTree algorithm appears to be the best choice since it achieved a great accuracy in a relatively short time, as compared to the others. Also of high interest was the HyperPipes result. In this case, it returned a good accuracy almost instantaneously. However, when applied to a bigger dataset and a set of images of distinct patients, the results of the HyperPipes algorithm happen to differ drastically.

Overall Evaluation

To avoid unfair comparisons of classifiers we have further evaluated some of the algorithms of Table 1 along with a variation on the neighborhood size (modified during the extraction of features). Hypothetically, one may consider that some classifiers perform better on a neighborhood of a certain specific size. In Figure 2, a chart that represents the accuracy (vertical axis) of each evaluated classifier (horizontal axis) versus the variation of the neighborhood size in pixels (orthogonal to the previous axes) is shown. The assessed CT images were 512x512 pixels wide.

The accuracies in Figure 2 were achieved using 66% random-selected split method as test mode from the data of 16 patients. The 66% split test mode is defined as randomly selecting 66% of the instances for training and using the remaining for evaluation of the predictive model. The reason for choosing the split method and 16 patients was to reduce the huge convergence time due to the great amount of data and, consequencely to speed up the analysis. The extracted features composed datasets are approximately 1.5 gigabytes for each neighborhood size that was provided to each classifier. The

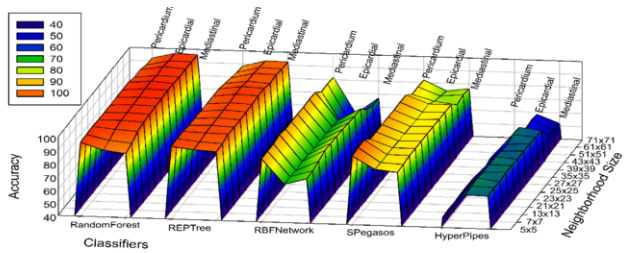

Figure 2 – Accuracies of selected classifiers versus pixels neighorboods of distinct sizes.

period to train and evaluate the predictive model was, in some cases, up to 20 minutes for each possible combination of neighborhood size and classification algorithm.

The five algorithms shown in Figure 2 were the quickest on this large dataset (16 patients). The HyperPipes was the fastest and always converged virtually within 0.5 seconds but, in this case, the best accuracy that it could achieve was around 70%. We can state by this evidence that this algorithm is not generalizable. In other words, the algorithm overfitted to a single patient and failed to generalize the predictive model to a class instead of a single patient. It is a rather simple algorithm and, in fact, the achieved low accuracy was somehow supposed to happen, even in the convergence evaluation trial.

Due to the convergence time issue, we were not able to extensively assess all the possible sizes for the neighborhood in consideration for all the algorithms shown in Table 1. The REPTree algorithm did not converge remarkably faster than the remaining decision tree algorithms evaluated on this large dataset. The RBFNetwork was faster than RandomForest and SPegasos was slower but both achieved lower accuracies. SPegasos was the slowest among the algorithms in Figure 2. RandomTree and DecisionStump were just a little faster than RandomForest and REPTree but the accuracies were significantly lower; therefore, they were disregarded in the second evaluation due to the massive presence of decision tree algorithms. The J48Graft returned similar accuracies if compared to RandomForest but its convergence was approximately 1.4 times slower and, so it was impracticable to evaluate all the neighborhood sizes for this classifier. The SimpleCart, Naïve Bayes, J48 and SMO took more time to converge on the large dataset than SPegasos, therefore, they could not be precisely evaluated in the second trial.

Visualization

Figure 3 compares a single manually segmented slice (left) to the result of the proposed automatic segmentation (right). Green denotes the mediastinal fat, red represents the epicardial and blue corresponds to the pericardium. All the colored pixels represent pixels within the fat range for a CT image, therefore, there are some discontinuities on the images. Figure 4 corresponds to the same patient shown in Figure 3 but reconstructed in a 3D model. It is possible to distinguish the contour of the heart based on the epicardial fat (red color).

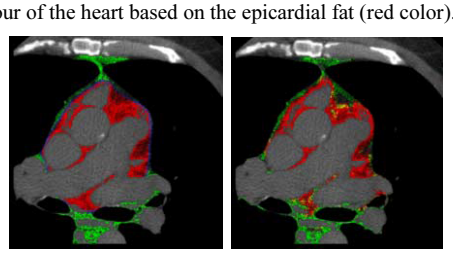

Figure 3 – Manually (left) and automatically segmented slice (right).

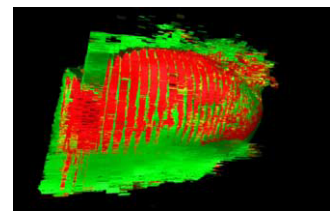

Figure 4 – 3D model of the automatically segmented patient.

Table 2 compares the results obtained by the proposed methodology to the four main related works. Barbosa *et al.* [14] and Kakadiaris *et al.* [13] use semi-automated methods, while Shahzad *et al.* [15] and Ding *et al.* [16] use fully automatic methods. The first column of the table indicates the rate of successful automatic segmentations, which are usually observed by a physician. The second column is the Dice similarity index and the third is the true positive rate. All these four works only segment the epicardial fat, therefore, we only compare our epicardial fat segmentation rates.

Table 2 – Comparison of results

Authors	Successful	Dice	T.P.
Barbosa *et al.*	10% (4/40)	-	-
Kakadiaris *et al.*	-	-	85.6%
Shahzad *et al.*	96.9% (95/98)	89.15%	-
Ding *et al.*	-	93.0%	-
This work (epicardial)	100% (82/82)	97.9%	98.3%

Conclusion

The proposed automated method achieved the best results with no need for placement of any control point, the mean accuracy for both the epicardial and mediastinal fats was 98.4% with a mean true positive rate of 96.2%. We are the first to propose an automated segmentation of the mediastinal fat and a unified methodology for the automated segmentation of both types of fat. Despite the processing time issues of our approach, this is still feasible for real time segmentation if properly adjusted. Although it requires approximately one day to segment a single patient, some heuristics could be used to speed up the classification step while an extensive selection and evaluation of features could grant an overall speed improvement. The speed up gain is also strongly related to the meticulousness of the approach. If a faster segmentation is desired, a per-area classification instead of a per-pixel classification may be applied and it should return worse but still adequate results.

Ensemble methods use multiple learning algorithms to obtain better predictive performance. In this work, we have selected a single classification algorithm (Random Forest) to segment the patients. As a further improvement, the RandomForest could be combined to the J48Graft and, perhaps, to the REPTree algorithms to increase the accuracy of the predictive

model. These three algorithms, RandomForest, J48Graft, and REPTree, were the best in our performance analysis.

Fusing Heterogeneous Data for Alzheimer's Disease Classification

Parvathy Sudhir Pillai[a], Tze-Yun Leong[a,b], Alzheimer's Disease Neuroimaging Initiative

[a]*Medical Computing Laboratory, School of Computing, National University of Singapore, Singapore*

Abstract

In multi-view learning, multimodal representations of a real world object or situation are integrated to learn its overall picture. Feature sets from distinct data sources carry different, yet complementary, information which, if analysed together, usually yield better insights and more accurate results. Neuro-degenerative disorders such as dementia are characterized by changes in multiple biomarkers. This work combines the features from neuroimaging and cerebrospinal fluid studies to distinguish Alzheimer's disease patients from healthy subjects. We apply statistical data fusion techniques on 101 subjects from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database. We examine whether fusion of biomarkers helps to improve diagnostic accuracy and how the methods compare against each other for this problem. Our results indicate that multimodal data fusion improves classification accuracy.

Keywords:

Multimodal;Data fusion; Heterogeneous; Alzheimer's disease.

Introduction

Multimodal data fusion refers to the fusion of multiple data sources, their associated features, and (or) intermediate decisions to perform an analysis task [1]. This multimodel method has found widespread use in areas such as multimedia and sensor analyses to integrate views obtained from audio and video signals, texts and images, and others. Recent studies in medical informatics have benefitted from combining multiple data sources to better understand disease processes. In this paper, we study the impact of multimodal data fusion on classifying Alzheimers' Disease (AD) patients.

Dementia is a spectrum of neuro-degenerative disorders that lead to memory and cognitive decline, severe enough to disable a person to perform activities of daily living. AD, the most common subtype, affects close to 75% of the demented population. As of 2010, there are around 36 million affected individuals worldwide, and an enormous amount is spent on their care [2]. No definitive prevention methods/cures are available for AD. Hence, we need efficient methods to screen and study the disease early on, so that timely interventions may delay its progression.

Dementia severity is assessed by psychometric tests like Mini Mental State Examination (MMSE) and Clinical Dementia Rating (CDR), neuroimaging, protein and genomic tests, and others. Biomarkers acquired from these tests provide indicators about a person's state. The sensitivity of biomarkers varies over the stages from normal aging through Mild Cognitive Impairment (MCI) to Dementia, as evident from Figure 1 [3]. Recently, pattern classification methods have been applied to analyze these biomarkers in combinations [10, 11, 12], as the information from different biomarkers is complementary in nature. While structural Magnetic Resonance Imaging (s-MRI) has good spatial resolution to identify atrophied brain regions, functional imaging such as Fluodeoxyglucose Positron Emission Tomography (FDG-PET) reveals hypometabolism in the affected brain areas. Protein studies of the Cerebrospinal Fluid (CSF) indicate the presence of beta amyloid (Aβ42) and tau (τ) proteins which form plaques and tangles in the brain, characteristic of AD. Combining multiple related data sources yields a fused representation of the object under study. Analysing this representation yields a comprehensive picture that benefits from the interplay of statistical dependences of the data sources. Further, the analysis reduces noise in the data by averaging it out over the independent data sources.

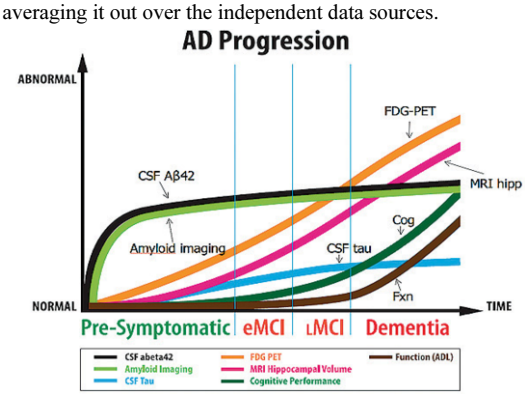

Figure 1. Biomarker sensitivity to Dementia related changes in the human brain across stages. Used with permission from the website of National Institute of Aging [3].

Motivated by these facts, we examine the effectiveness of statistical methods for fusing biomarker data to distinguish AD patients from healthy subjects (HS). On a subset of data from ADNI, we compare three data fusion methods based on:

1. Canonical Correlation Analysis (CCA)
2. Multiple Kernel Learning (MKL)
3. Collective Matrix Factorization (CMF)

While CCA ensures that the fused representation has maximally correlated features, MKL learns the optimal way to combine the features to yield the best classification accuracy. CMF is a comparatively recent method that jointly factorizes matrices that share a common dimension. We explain, implement, and test these methods on the ADNI data to compare their accuracies of classification over unimodal and prior multimodal studies.

Related Work

Quantitative fusion of medical data is very challenging because of the heterogeneity of the modalities. Two main approaches exist for combining heterogeneous information. The first approach, known as early fusion, aggregates data at the feature level into a single representation before analysis. Kernel space combination proposed by Lanckriet et al. to combine amino acid sequences and gene expressions [4], vector concatenation of Principal Component Analysis (PCA) reduced features used by Lee et al. to fuse mass spectrometry and histology information [5], and Artificial Neural Networks (ANN) used by Baez et al. to integrate various neuropsychological test scores [6] all fall under this category. Though these methods preserve inter-source dependencies, they suffer from the curse of dimensionality and hence require a large amount of training data to learn a relevant model. The second approach, known as late fusion, combines decisions from models learnt on the individual feature spaces. Various rules such as weighted combination [7], majority voting [8], likelihood maximization [9] of the decision variables have been proposed. As the fusion is at the level of decisions, there are no concerns with the dimensionality of the data. However, these methods fail to retain inter-source dependencies.

Multimodal assessments of AD and MCI were found to classify diseased individuals more accurately than unimodal methods. Zhang et al. combined MRI, PET and CSF biomarkers using multiple kernels and a coarse grid search to find the optimal kernel combination on a Support Vector Machine (SVM) classifier [10]. As compared to this discriminative approach which models the conditional distribution of variables for predicting the class labels from features, Young et al. used a variation of kernel combination with a generative Gaussian Process (GP) classifier [11]. This generative approach models the joint distribution of variables and uses likelihood maximization to learn the optimal parameters; it is shown to perform on par with the earlier discriminative approach. Gray et al. applied Random Forest (RF) proximity measures to combine MRI and PET features [12]. Though these methods provide good classification accuracy, they cannot in general support understanding of the data and their interactions. Moreover, these methods do not handle missing data or specific data types such as ordinal data.

There are three general multiview learning approaches: weighted view combination, multiview dimension reduction, and subspace learning. Inspired by the promising results of previous multimodal analyses, we aim to explore the effectiveness of three representative methods from the categories, CCA (multiview dimension reduction), MKL (weighted view combination), and CMF (subspace learning), for combining multimodal biomarker features for AD diagnosis. While Zhang et al. [10] and Young et al. [11] used MKL, only linear combination of kernels was explored. CCA and CMF have not been used in the context of fusing biomarkers for AD diagnosis. The fused representation should generalize well to related problems of supervised learning such as classification and unsupervised learning for understanding the association between biomarkers.

Methods

The goals of data fusion are as follows:

1. Reducing the dimensionality of the participating views, so that the fused representation has the most representative components of the individual views.
2. Explaining the nature of relationships between datasets by measuring the relative contribution of each variable to an analysis task.
3. Learning a joint subspace from the different views that supports interpreting the datasets well enough to handle missing data.

We explore the ability of three popular data fusion techniques in attaining these goals. In the implementations, we consider biomarker data as matrices where the rows correspond to subjects and columns to features.

Canonical Correlation Analysis

CCA seeks to find linear projections of two sets of multidimensional variables, so that the projections are maximally correlated [13]. Correlation as a relationship is heavily dependent on the chosen coordinate system; therefore, even if there is a strong linear relationship between two sets of multidimensional variables, the relationship might not be visible as a correlation.

Mathematically, if x and y are two multidimensional random variables with zero mean and $w_a{}^T x$ and $w_b{}^T y$ are their corresponding linear projections, maximizing their correlation, ρ, corresponds to solving Equation (1). If C_{ab} is the cross-covarianve, C_{aa} and C_{bb} are the auto-covariance matrices,

$$\max_{w_a, w_b} \rho = \frac{w_a^T C_{ab} w_b}{\sqrt{w_a^T C_{aa} w_a}\sqrt{w_b^T C_{bb} w_b}} \quad (1)$$

CCA is often formulated as a generalized eigenvalue problem where the maximum correlation corresponds to the largest eigenvalue.

$$\begin{pmatrix} 0 & C_{ab} \\ C_{ba} & 0 \end{pmatrix} \begin{pmatrix} w_a \\ w_b \end{pmatrix} = \rho \begin{pmatrix} C_{aa} & 0 \\ 0 & C_{bb} \end{pmatrix} \begin{pmatrix} w_a \\ w_b \end{pmatrix} \quad (2)$$

Several extensions to the original CCA have been proposed to include more than two views, and to find non-linear relationships between views. Currently, we restrict ourselves to the linear version because it is faster and involves easily interpretable components. The most commonly used approach to include three or more, say p data sources is to sum up the correlations (mCCA). The generalized eigenvalue problem then accounts for maximizing the sum of the correlations. This formulation is depicted in Figure 2.

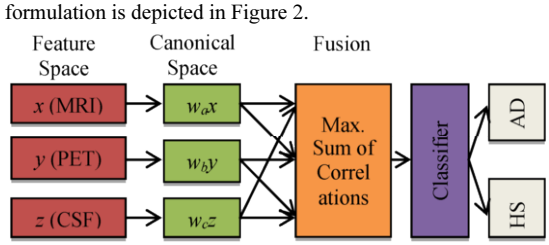

Figure 2. CCA based classification

Tripathi et al. [13] proposed a two step procedure for summing up the correlations. First, the correlations within a data source are removed by a process called whitening. This is done by multiplying the individual data matrices with the square-root of their respective covariance matrices to find components shared between the views. Second, Principal Component Analysis (PCA) is applied to the column-wise concatenation of the whitened data sources. The original data is further projected on to the largest d PCA coefficients. The choice of d is based on the amount of shared variance. The smallest d, after which there is no significant increase in shared variance, is the optimal dimension of of the projection. The projection yields the fused representation which is then used by a classifier to learn the model.

Multiple Kernel Learning

Kernel methods such as SVM, which are based on similarity measures between data points, have been used with great success for dimensionality reduction and classification. Kernelization projects the native space data to a higher dimensional feature space. Non-linear relations between variables in the original space become linear in the transformed space. The projection, ϕ is given by the mapping,

$$\phi: x = (x_1, \dots, x_n) \rightarrow \phi(x) = (\phi_1(x), \dots, \phi_N(x)) \quad (3)$$

To project the data we use the kernel trick, wherein we apply kernel functions, $\kappa_1, \dots, \kappa_p$, to get the corresponding kernel matrices $K_1, \dots, K_p$. Each kernel, $K = <\phi(x), \phi(z)>$ is an inner product of data points. Examples of kernel functions include the linear, radial bias function and others.

Using more than one kernel often produces a better model. In MKL, data is represented as a combination of base kernels [10]. Each base kernel represents a different modality / feature of the entity. MKL seeks to find the optimal combination of the base kernels so that the analysis tasks which follow are benefitted the most. Classification tasks are especially well represented through MKL, as the optimal combination is the one that gives the maximum classification accuracy.

The dual form of MKL optimization, as it is solved by conventional solvers like LIBSVM [14], is

$$\max_{\alpha} \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \sum_{m=1}^{p} \beta_m k^{(m)}(x_i^{(m)}, x_j^{(m)})$$
$$s.t \quad \sum_{i=1}^{n} \alpha_i y_i = 0; 0 \le \alpha_i \le C; i = 1, \dots, n \quad (4)$$

From a set of n training samples, the features of the i-th sample from the m-th modality are in the vector $x_i^{(m)}$, and its corresponding class label, y_i is either +1 or -1. α's are the Lagrange multipliers which are the variables obtained on converting the primal support vectors to the dual problem. The kernel function applied on each pair of the samples from a modality m, is $\mathbf{k}^{(m)}$. The weights on the m-th modality kernel, represented as β_m are optimized using a grid search or as a separate optimization problem with fixed α. For each new test sample, s, the kernel functions are computed against the training samples. The MKL overview is depicted in Figure 2.

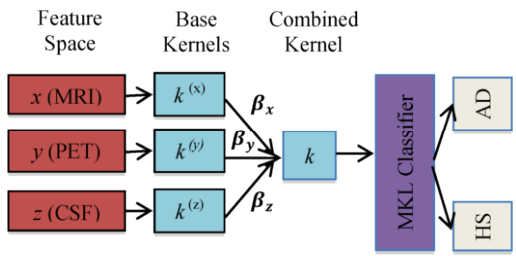

Figure 3. MKL based classification

Zhang et al. [10] and Young et al. [11] used coarse grid search and likelihood maximization approaches respectively, to find the optimal kernel weights, β. They used only one linear base kernel for each of the feature sets and constrain the β's to sum to 1 ($\beta: \|\beta\|_1 = 1; \beta \ge 0$). This however may yield sparse solutions with certain kernels not being well-represented. Recent research has shown that including the base data sets in more than one kernel each differing in their selection of kernel parameters, improves performance [15]. Regularized MKL based on $l2$ norm ($\beta: \|\beta\|_2 = 1; \beta \ge 0$) and $l12$ mixed norm ($\beta: \|\beta\|_2 \le 1; \beta \ge 0$) for constraining β have been proposed. Though $l2$-regularized MKL yields non-sparse solutions, it no longer remains a convex optimization problem and hence is difficult to solve as the sample size increases. $l12$-regularized MKL involves more than one base kernel from a single modality. It enforces sparsity across modalities, while allowing more than one discriminative kernel to be chosen from the same modaility. In other words, there is sparsity across modalities and non-sparsity within modalities, thereby making it a convex optimization problem.

Collective Matrix Factorization

CMF is a technique in relational learning for predicting the unknown values of a relation, given a database of entities and their relations. It learns the low-rank approximations of the matrices which share entities [16].

Given a set of M matrices which describe the relations among E entities, CMF approximates them to low-rank factorizations. The matrices are approximated as a rank-L product and additional row and column bias terms. If r_m and c_m are the entity sets corresponding to the row and column respectively of the m-th matrix, on factorization, its element in the i-th row and j-th column is represented as:

$$x_{ij}^{(m)} = \sum_{l=1}^{L} u_{il}^{r_m} u_{lj}^{c_m} + b_i^{(m,r)} + b_j^{(m,c)} + \varepsilon_{ij}^{(m)} \quad (5)$$

Where, $[u_{ik}^{(e)}]$ is the rank-L approximation of entity set e, $b_i^{(m,r)}$ and $b_j^{(m,c)}$ are the row and column biases respectively and $\varepsilon_{ij}^{(m)}$ is the element-wise noise. The matrices which share the same entity set share the same low-rank matrix approximation. Recent works arrange all the M matrices into a large square grid, whose dimension is the sum of cardinalities of all the entity matrices. However, in the resulting symmetric matrix, Y, only blocks corresponding to the M matrices are observed and the rest of the elements are left unobserved. The CMF model is then formulated as a symmetric matrix factorization,

$$Y = UU^T + \varepsilon \quad (6)$$

where, U is the column-wise concatenation of different $[u_{ik}^{(e)}]$ matrices and bias terms are dropped for simplicity [16].

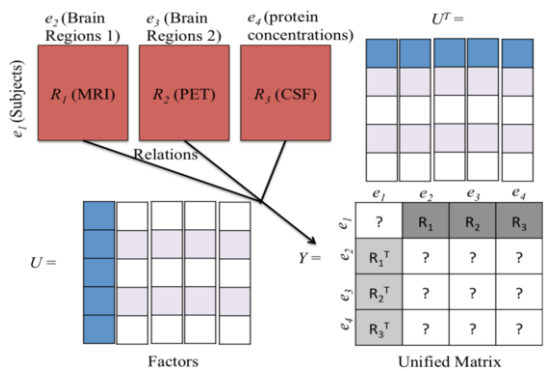

Figure 4. CMF based modeling

Experiments

We implemented the multimodal fusion approaches described above, for integrating the MRI, PET and CSF biomarkers. We used the fused representation to classify a selected study group into patients with AD from healthy subjects (HS). The fused approach is considered successful if the classification task is performed with greater accuracy along with better precision and recall against unimodal classifications. Along with the unimodal approaches, we evaluated the classification of a concatenated data vector comprising data from the three modalities and used it as a baseline study.

The three modalities: MRI, PET and CSF, complement each other in the information they hold [10]; this enables us to draw better insights in a classification task. We used these three biomarkers specifically because, as shown in Figure 1, they compare better than the others in identifying AD early on.

Data

The data for evaluation was obtained from the Alzheimer's Disease Neuroimaging Initiative (ADNI) [17]. We worked on baseline MRI images and FDG-PET images that were acquired within 30-60 min post injection. The image details are available at the ADNI website: http://adni.loni.usc.edu/. MMSE (0-30) score of >=27 and CDR (0-3) of 0 are considered normal. The demography of the subjects that we considered are shown in Table 1.

Table 1– Subject Demography

	AD (n = 51; 18F/33M)			HS (n = 52; 18F/34M)		
	Mean	SD	Range	Mean	SD	Range
Age	75.2	7.4	59-88	75.3	5.2	62-85
MMSE	23.8	2.0	20-26	29	1.2	25-30
CDR	0.7	0.3	0.5-1	0	0	0

Preprocessing

The sequence of steps for processing the MRI images included setting the origin to the Anterior Commissure (AC), correcting intensity inhomogeneities, and performing skull stripping. As grey matter atrophy is a prominent feature in AD patients, we segmented the images into grey, white matter and the CSF. This segmentation and the subsequent steps were done using the Statistical Parametric Mapping (SPM) 8 toolbox [18]. To standardize the images of all the subjects, they were normalized to a study specific template created by the SPM DARTEL toolbox [19]. The PET images were co-aligned to the corresponding MRI image using SPM8. Masks of 83 brain regions enlisted in the atlas prepared by Kabani et al. [20] were created using a tool called WFU-PickAtlas [21]. These masks were imposed on the segmented gray matter and PET images to obtain the regional grey matter volume and the average intensity measurements respectively. Thus, we obtained a 1×83 sized feature vector per subject for each of the imaging modalities. The CSF values obtained from ADNI were represented as a 1×3 sized vector per subject representing the total tau, Aβ42 and p-tau values respectively.

We implemented CCA and MKL fusion methods in MATLAB and used the R library 'CMF', for CMF. We tested the individual modalities and the concatenated feature vector (baseline) on the following classifiers:

SVM –This discriminative classifier is accepted to be standard for binary classification. We used the popular LIBSVM [14] tool for our experiments. With unimodal data we used an RBF kernel with default parameters.

GP –We used the GPML toolbox [22] and followed Young et al. [11] for the choice of covariance, mean, likelihood and inference functions.

RF – As an ensemble classifier, we used a MATLAB version of R language's RF library. The number of trees in the classifier were varied according to the dimensionality of the dataset under consideration.

Each method was tested using 10-fold cross validation, categorizing subjects into ten groups based on a random permutation. Nine groups were used for the learning phase and the remaining group formed the test set. The accuracy, precision and recall of the classification tasks were studied. Three prior works in multimodal AD classification were reimplemented and tested with our dataset.

Results

The results of our experiments are tabulated in Table 2. It is evident that a simple concatenation of the feature vectors (SVM (c), GP (c) and RF (c)) provides better classification results than unimodal tests. Prior multimodal biomarker based methods [10, 11, 12] have better classification accuracy than the baseline study (feature concatenation) as expected. However, the results are even better for classification on the fused representation obtained from the statistical methods like CCA and CMF.

Discussion

The concatenated feature vector consistently performs better across the three types of classifiers than individual biomarkers because of their complementary information. The poor performance of the baseline study in which there is no kernel combination, against the prior multimodal analyses of Zhang et al. and Gray et al. [10, 12], is due to the inclusion of all features and not just those which contribute to classification.

The MKL formulation based on *l12* mixed norm performs worse than Zhang et al.'s [10] but better than Young et al.'s [11] both of which are *l1* norm based. As the mixed norm enforces group sparsity, it chooses features common across all participating modalities. In comparison, *l1* norm and Gray et al.'s [12] RF based method choose features individually across modalities and ignores intermodal relationships. From this we understand that the common feature constraint may overlook certain modality specific features aiding classification.

mCCA and CMF both perform better than the rest of the methods. These methods learn a generic model of the biomarkers, not specific for classification. But they perform the best on classification task as well. This is because the generic model learnt from these techniques is built only on those relevant features or components that are statistically dependent across modalities. Though mCCA in its current form is incapable of handling missing entries it may be extended to handle them. CMF performs slightly poorer than mCCA in the classification task but is the most generic model.

The three methods compare as follows, with respect to achieving the goals of data fusion:

1. mCCA is effective in data exploration to find if there are any associations between the data sources. It saves what is shared between the views and ignores variations within, thereby achieving goals 1 and 2.
2. If the goal is only supervised learning, MKL methods, *l12* and *l1* based optimization [10, 11], can be applied directly as they learn the most distinguishing multimodal features, satisfying goal 1. However, such methods fail when there is missing data. Moreover, these methods lack a proper generative model for each view, and hence cannot be used for the task of understanding the data.
3. CMF handles missing entries by treating them as test data and allows multiple likelihood functions for modeling the data. The benefit of using CMF is that it identifies common factors shared between matrices and factors specific to individual matrices. Matrix factorization results in dimensionality reduction and thus satisfies the three goals of data fusion.

Conclusion

We examined multimodal data fusion on a dataset consisting of heterogeneous biomarker data. We used three categories of

fusion methods based on CCA, MKL and CMF. Further, we used the resultant fused representation for classifying AD patients. We found that classifying based on the fused representation that preserves intermodal relationships yields better results than unimodal classification. Amongst the three methods, mCCA gives the best accuracy on our dataset closely followed by the CMF based method.

Table 2– Region of Interest Based Classification

			Precision		Recall	
Data	**Method**	**Acc.**	**AD**	**HS**	**AD**	**HS**

Abstract

The Diagnostic and Statistical Manual (DSM) has served as the gold standard for psychiatric diagnosis for the past several decades in the USA, and DSM diagnoses mirror mental health and substance abuse diagnoses in ICD-9 and ICD-10. However, DSM diagnoses have severe limitations when used as phenotypes for studies of the pathophysiology underlying mental disorders, as well as for clinical treatment and research. In this paper, we use a novel approach of deconstructing DSM diagnostic criteria, and using expert knowledge to inform feature selection for unsupervised machine learning. We are able to identify clusters of symptoms that stratify subjects with the same DSM disorders into cohorts with increased clinical and biological homogeneity. These findings suggest that itemized self-report symptom data should inform a new taxonomy for psychiatry, and will enhance the bi-directional translation of knowledge from the bench to the clinic through a common terminology.

Keywords:

Psychiatry; Taxonomy; Unsupervised Learning; Clinical and Translational Informatics

Introduction

The Diagnostic and Statistical Manual of Mental Illness (DSM-V) is the current clinical psychiatric classification system in the United States for mental illness and substance abuse disorders [1]. When a patient is given a DSM diagnosis, the clinician asks the patient about the presence or absence of numerous symptoms, and then uses multiple DSM algorithms to determine the best diagnosis for the patient. There is a growing acceptance that DSM syndromes have severe limitations when used as phenotypes for identifying biomarkers associated with mental illness. Whether the symptom data that is ascertained during the diagnostic process can be used more effectively as phenotypes for biological inquiry into the pathophysiology of mental illness remains unclear. The purpose of this study is to determine if atomic level symptom data that is regularly ascertained by mental health practitioners can be effectively used to develop phenotypes that can identify clinical cohorts of psychiatric patients with pathophysiological homogeneity. As these data are already ascertained as part of the normal clinical workflow in psychiatry, and are frequently reported in the medical record, they can theoretically be used to phenotype clinical populations, facilitating cohort identification for biomarker identification, and enabling observational studies on outcomes effectiveness in different cohorts. These studies might in turn lead to the identification of biomarkers that can be used to stratify psychiatric populations in the future, improving diagnosis, treatment, and outcomes in these populations.

The current psychiatric classification system, the DSM, was initially developed after World War II, motivated to a large degree by the need for the Armed Forces to monitor the prevalence of and treat mental illness in soldiers who returned from the War. DSM I in 1952, and DSM II in 1968, were both rooted in psychodynamic psychiatry, in line with the legacy of psychoanalysis (e.g. beginning with Freudian Theory). With DSM III, the decision was made to take an "atheoretical" approach, and develop a classification system based on patterns of symptoms that clustered together, as agreed to by expert consensus in committee meetings, without the use of empirical data, and divorced from explanatory models of the etiologies of these disorders [2]. Studies showed that this new approach vastly improved inter-rater reliability with respect to the psychiatric diagnosis patients were given [3]. While the approach presumed that the categories reflected underlying pathological processes, no quantitative data or biological markers have been included in the DSM thus far.

Since 1994, the DSM-IV has served as the gold standard in psychiatric treatment and research [4]. Though DSM-5 was officially released in May of 2013, the vast majority of USA clinicians are still transitioning from DSM-IV to DSM-5. As such, DSM-IV disorders have served as phenotypes by which clinicians diagnose and treat patients and obtain reimbursement, as well as phenotypes for basic science, translational, and clinical research carried out in the domain of psychiatric illness. Furthermore, DSM-IV syndromes have been shown to have a great deal of similarity to ICD-9 and ICD-10 diagnoses, so the results of studies using the DSM are highly generalizable to populations worldwide [5].

Much has been written about the limitations of the DSM-IV with respect to the use of its syndromes as phenotypes for use in both clinical practice and research. Below, we will briefly review the most salient points as they relate to phenotypic heterogeneity, limitations of syndromes in identifying biomarkers, and informatics challenges faced when attempting to construct phenotypes that define more clinically and biologically homogenous groups from symptom data ascertained using DSM-IV syndromes as phenotypes.

DSM-IV defines 137 Syndromes/Disorders across 15 categories. Syndromes are by definition binary, and there are no signs (objective or quantitative markers) associated with DSM-IV syndromes. Symptom overlap (e.g. sleep disturbances, guilt) across syndromes (e.g. Major Depressive Disorder (MDD), Post Traumatic Stress Disorder (PTSD)), resulting in clinical presentations where patients are defined as having several "comorbid" psychiatric disorders, complicating

diagnosis and treatment for the clinician, with a paucity of evidence based treatment algorithms for multiple comorbid psychiatric disorders.

DSM-IV phenotypes also have limited clinical utility, as two patients with the same DSM-IV Syndrome may not share any of the same symptoms. Due to the structure of DSM-IV Syndromes, many different combinations of symptoms meet the criteria for the same Syndrome. For example, with Major Depressive Disorder (MDD), "depressed mood" or "anhedonia" AND 5 out of 9 other symptoms are required, leading to 112 different possible symptom presentations. As some of the symptoms are underspecified (e.g. sleep disturbance may refer to hypersomnia or insomnia), it is possible for two patients to have MDD without sharing ANY of the same symptoms. Of note, this lack of syndromic specificity remains present in DSM-5, as many major syndromes, including MDD have not been altered at all for the new version.

This phenotypic heterogeneity also has severe limitations for clinical and translational research. Clinical trials have shown that several classes of medications that are equally efficacious across several syndromes, and are used clinically across several DSMIV higher level classes(e.g. Mood Disorder and Anxiety Disorders, Mood Disorders and Psychotic Disorders) arguing for the fact that the overlap of symptoms across these disorders actually reflects the presence of common pathophysiology present across different DSM-IV syndromes.

There has been an abundance of articles discussing how the lack of biological validity underlying the creation of DSM-IV Syndromes has resulted in a lack of robust biomarker findings within syndromes [6]. In addition to the fact that DSM-IV Syndromes have overlapping symptoms, recent studies have confirmed that specific genetic variants are present in subjects with multiple DSM-IV Syndromes, and not in unaffected controls. One recent seminal study showed that variants in the CACNA1C calcium channel are associated with several psychiatric syndromes, including autism spectrum disorder, attention deficit hyperactivity disorder, bipolar affective disorder, and major depressive disorder [7]. Additionally, several other biological markers, for example non-suppression of cortisol by dexamethasone, have been found to be significantly different in affected individuals as opposed to controls, in multiple psychiatric syndromes [8]. However, to our knowledge, there has not been a comparison of psychiatric symptom presentation similarities across these syndromes, with a focus on how this relates to these biomarker differences.

Finally, the current terminology of the DSM-IV nosology makes it difficult to investigate symptoms across syndromes, due to a decision made with DSM-III that no symptom could be replicated in two Syndromes [9]. Though it is unclear if this rule has explicitly followed during the creation of DSM-IV and 5, manifestations of this limitation undoubtedly exist in DSM-IV and DSM- 5, making it challenging at this time to use existing NLP and text-mining methods to automatically identify symptoms across syndromes within narrative text, or even structured interview data. The APA has increasingly published measures to investigate more primary psychiatric symptoms in clinical populations, but the use of these measures has not yet translated into clinical care, nor is it yet reflected in the literature [1].

In view of a preponderance of shortcomings, major stakeholders in mental health treatment and research have publically presented alternate systems for codifying current and future knowledge to inform the understanding of mental illness, most notably Precision Medicine and the Research Domain Criteria (RDoC)) [10]. However, these ideas are still very much in the development stage, and there has been a paucity of discussion as to how these taxonomies will be integrated with clinical psychiatry. Generations of psychiatrists, including those who are currently teaching residents and medical students, have been trained using the DSM, and routinely evaluate patients using symptom level data with the ultimate goal of identifying the most appropriate DSM disorder or disorders for the patient based on the constellation of symptoms present in the clinical presentation.

It is with this background that we propose to identify groups of patients that cluster together based on itemized psychiatric symptom level presentation, regardless of how these symptoms have been used to classify DSM Syndromes up until this point. We then propose to identify biomarkers that are associated with these different clinical symptom presentations to show that self-report symptoms have utility in developing a clinically relevant and biologically valid taxonomy for psychiatry. Few studies have looked at the correlation of psychiatric symptoms with biomarkers, independent of DSM-IV syndromes, across a patient population. The vast majority of studies which have looked at itemized symptom level data in the DSM-IV in any manner, have looked only at a subset of symptoms involved in one to three closely related DSM disorders, most notably within childhood disorders such as autism and ADHD, and cognitive disorders including Alzheimer's. There are two studies we know of that have looked at the DSMIV symptoms in total, but with different foci than described in this proposal [11, 12] We have not been able to identify any studies that have looked in total at all symptoms across all principal DSM Syndromes within a dataset where patients carry the diagnosis of more than one DSM Syndrome.

Studies have shown that it is possible to classify psychiatric patients into groups of subjects with increased pathophysiological and disease course homogeneity using machine learning algorithms with various types of biomarker data [13]. This classification is possible even without full understanding of the pathophysiology underlying the disorder. These methods also suggest a direct translation from academic research to clinical practice, where they may ultimately be used to diagnose patients in the clinical setting.

We present the analyses of a multi-modal dataset comprised of combat veterans, 33 % of whom have been given a DSMIV diagnosis of PTSD. We used unsupervised learning methods, including hierarchical cluster analysis and K means clustering, with the goal of identifying robust groups of patients that cluster together with respect to clinical symptoms and biomarkers.

Materials and Methods

Data

We conducted secondary analyses ascertained through VA and DoD funding at the San Francisco Veterans Administration Health Center. Details of the Gulf War (GW) study have also been published [14, 15]. In brief, there were 292 Gulf War Veterans, 85% of whom were male, and 75% who were combat trauma exposed. Given the small sample size and the relatively large number of clinical and biological markers to be used in the analyses, only the males were included in this study. 50% of those included had comorbid DSM-IV diagnoses of Lifetime Alcohol Abuse or Dependence, and 40% had comorbid DSM-IV diagnoses of Major Depressive Disorder.

The four main data types used in this study are self-report clinical symptom data, and three different modalities of biomarker data: neuropsychological data, magnetic resonance imaging data, and neuroendocrine data. Ascertainment of these data are briefly described below.

The self report clinical data that was used consists of 136 clinical self-reported clinical features, 21 from the Beck Depression Inventory (BDI;, a scale developed and used to diagnose Major Depressive Disorder, 19 from the Clinician's Assessment for PTSD (CAPS), a scale used to diagnose PTSD in clinical populations and 90 items from the Symptom Check List -90 (SCL-90), a clinical questionnaire developed to measure psychiatric symptoms across 10 psychiatric domains, including mood, psychosis, anxiety, eating, and sleep disorders. Also included were 5 binary measures of significant substance use or dependence, for alcohol, cannabinoids, stimulants (e.g. methamphetamine), cocaine, and hallucinogens.

The ascertainment of neuropsychological and imaging data was described in detail in prior publications. Briefly, the neuropsychological battery used assessed three domains of cognitive functioning: verbal memory; visual memory and visual–spatial skills; and attention, working memory, and processing speed with 10 normalized scores reported for each subject. Subjects were studied with MRI; multislice 1H MRSI measures were ascertained. Hippocampal determination was based on MPRAGE images and carried out semi-automatically using a high dimensional brain-mapping tool and values were divided by total intracranial volume for normalization. Subjects also completed a low-dose (0.5 mg) dexamethasone (DST) suppression test challenge using salivary cortisol [8] , and area under the curve (AUC) for both day 1 and day 2 of the test were used in these analyses. Baseline serum cortisol level was also ascertained.

Feature Selection

A hybrid approach was attempted to reduce redundancy across clinical features: Features were first mapped to each other if a clinical expert (JR) determined the concepts they were identifying as being clinically equivalent (e.g. expected to result in the same answer if both questions were asked to the same patient in a clinical interview). A correlations matrix was also created for all clinical features, to identify features with a correlation coefficient of $\geq$ .90. Interestingly, there was no intersection between the two methods, and the decision was made to remove a feature based on correlation coefficient $\geq$ .90, resulting in 124 total clinical features that were ultimately used for the subsequent analyses.

Ideally we would have been able to use symptom data from the Structured Interview for DSM (SCID), the tool that was used to initially identify DSM Diagnoses. However, the data in this study has been generated without the SCID data, as we only currently have composite level syndrome data available from the SCID. We therefore mapped the complete CAPS, BDI, SCL-90, and Alcoholic and substance abuse portions of the SCID to all the SCID questions, and estimate that our data cover approximately 85 % of all symptoms ascertained in a formal SCID, with predominantly 75% of psychotic symptom data and 50% of OCD symptom data unaccounted for. However, as individuals were excluded from our study with a history of psychotic symptoms, we estimate that missing relevant symptomatic data are minimal.

Statistical Analyses

Individuals with > 15% data missing in any measures (clinical, imaging, endocrine, neuropsychiatric), were not included for any analyses that required that data type. Missing values were filled with median imputation. All data used in the analyses was standardized and normalized.

All statistical analyses were performed using R statistical programming software [16]. We used hierarchical clustering (*hclust*) with Ward's distance measurement. As multiscale bootstrap resampling *(pvclust)* provided no significant p-values (e.g. p<. 05) for any individual clusters, clusters were delineated using a dendrogram to visualize vertical distances in branching across clusters. We then performed K-means nearest (*kmeans*) neighbor clustering three different times, as clusters delineated with the *kmeans* algorithm are nondeterministic. We identified the optimal number of clusters from the K-means analyses by finding the bend in the plot of the within group sum of squares versus number of clusters. We then compared cluster solutions across all three K-means results with the hierarchical clustering results to determine robustness of clusters. Finally, we performed descriptive statistical analysis on imaging, neuropsychiatric, and neuroendocrine measures using ANCOVA to determine differences in biomarkers across clusters.

Results

Hierarchical agglomerative clustering using 124 features using Ward's method for determining distance between individuals produced the results shown in Figure 1. Visual inspection of dendrogram branching identified two, three, or five natural clusters. Multiscale bootstrap resampling provided no significant p-values (e.g. p<. 05) for any individual clusters. Three independent runs of K-nearest neighbor analysis also revealed that data ideally clustered into 5 groups that had a good to great degree of similarity with the hierarchical clusters (Cohen's Kappa Values .904, .897, .702).

Given the similarity of the multiple solutions and the determinism in using agglomerative hierarchical clustering, the five clusters delineated through hierarchical clustering were chosen for further analyses of biomarkers across clusters. Ancova with adjustment for age was calculated for all biomarkers in the data set. The most significant p-values, values without adjustment for multiple testing are shown in Table 1. In an effort to account for variance, a linear model was constructed using all variables that had unadjusted p-values approaching a level of significance in a Mancova analysis, with results for differences in biomarkers across clusters shown in Table 2.

To further gain insight into differences between the five clusters, we looked at the absolute values of individual symptoms across the five clusters, as shown in Figures 2a, 2b, and 2c. We also graphed mean values of all biomarkers across the five clusters to facilitate description of these five clusters both from the perspective of biomarkers, and of clinical symptoms. Graphs for the six biomarker variables that showed significance in the Mancova analyses, are shown in Figures 3a through 3f.

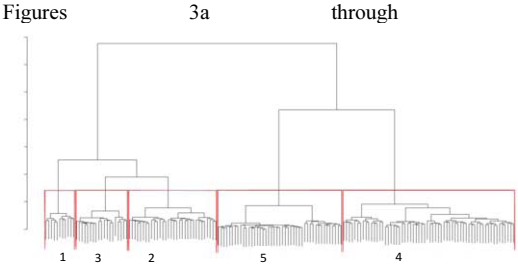

Figure 1-Hierarchical Clustering of Itemized Symptom Data

Table 1-Ancova of Clusters with Significant Biomarkers

Dependent Variable	Ancova p-value
Right Hippocampal Volume	.057
Dexamethasone Suppression Test	.004

Verbal IQ	.003
Performance IQ	.000
Right Hippocampal Volume	.417
Left Hippocampal Volume	.517

Discussion

In this study we show that statistical learning methods can be used with atomic level psychiatric symptom data to identify groups of patients with phenotypic and biological homogeneity. Perhaps the most surprising finding is that the clusters delineated are not associated with any "type" or "types" of symptoms as would have been expected from the DSM classification system. Instead, the 5 clusters are defined by the intensity of the majority of symptoms across all questionnaires, and hence, DSM Syndromes. In fact, with the exception of two neuro-vegetative symptoms associated with depression and one paranoia symptom, the subjects in Cluster 1 on average have worse values for all of the psychiatric symptoms than subjects in all of the other clusters. As would be expected, these subjects have a higher mean number of DSM–IV diagnoses, yet no single or even group of co-morbid diagnoses can partition them in the intuitive manner that hierarchical clustering is able to.

Cluster analyses delineated 3 clusters of patients that each contain significant numbers of individuals who meet criteria for PTSD (clusters 1, 2, and 4), as seen in Table 3. However, individuals in cluster 4 have much lower levels of subjective psychiatric symptoms than individuals in clusters 1 or 2, and significantly different (and arguably more "normal") biological markers across the neuropsychiatric data, imaging data, and neuroendocrine data. These findings are in line with the growing consensus that DSM phenotypes are underspecified, and lump together groups of patients that are too heterogeneous to use in clinical, translational, or basic science studies. While this study is obviously limited by the very small sample size and exclusion of female subjects, the fact that biologically and clinically relevant clusters were identified, provides support for the hypothesis that using data from larger psychiatric cohorts with these methods will greatly increase our current knowledge base in the psychiatric domain.

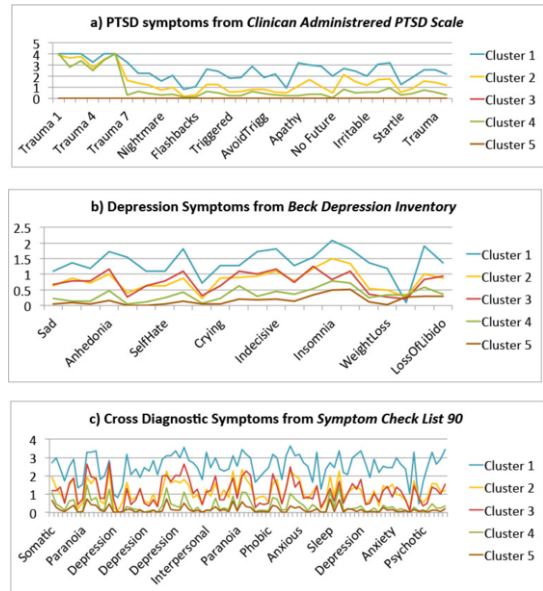

Figure 2- Mean itemized symptom data for each cluster

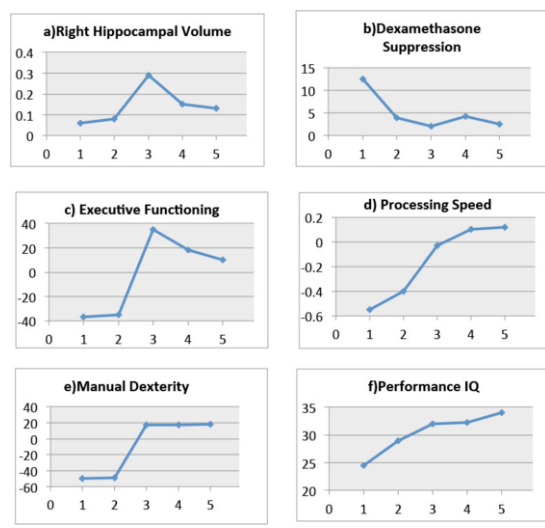

Figure 3- Normalized Mean Biomarker Values By Cluster: a) Right Hippocampal Volume, b)DST Area Under the Curve,c-e)Standardized Executive Functioning, Processing Speed, and Manual Dexterity, f)Performance IQ

The use of DSM diagnoses does not correlate with these clusters, but symptom data analogous to that used to delineate DSM diagnoses were used in these analyses. Therefore, these findings propose a method by which clinical stakeholders and basic science researchers in the mental health domain can communicate to delineate a taxonomy for psychiatry that is ultimately both clinically and biologically useful. Arguably, phenotype definition is the most pressing issue in psychiatry

Table 3-DSM-IV Diagnoses by Cluster Number

Cluster	Tot. #	PTSD	MDD	ALC	PTSD MDD	PTSD ALC
1	11	11	5	4	5	2
2	32	12	4	15	0	1
3	19	0	6	4	0	0
4	61	16	2	14	1	0
5	45	1	1	4	0	0

to date. DSM-5, released in May 2013, remains the clinical bible for psychiatrists, and its diagnoses, which map to ICD-9 and ICD-10, are necessary for billing insurance companies and Medicare. DSM-5 therefore remains the standard in medicine, and continues to be taught to medical students and residents. Yet one month prior to the release of DSM-5, the NIMH proclaimed that studies using DSM phenotypes will no longer be a priority for funding, strongly encouraging the use of the RDoCs [10]. While a biologically based taxonomy is the ultimate goal for psychiatry, as with all other domains of medicine, clinical psychiatry is far from being grounded by mechanistic biomarkers. The findings in this paper that individual symptoms that are regularly ascertained clinically are associated with changes across multi-modal biomarkers, gives support to the notion that symptoms may still be useful in psychiatry to both clinicians and researchers. In fact, there may be data within the multitude of large datasets already ascertained, that can be used to develop symptom based psychiatric phenotypes that can identify clinically and biologically homogeneous subpopulations, both for diagnostic purposes, and that will have clinical utility and be able to further inform phenotype construction in a biologically based taxonomy.

It seems likely in the near future that patients will continue to present with self-report symptoms that will guide the evaluation and treatment of patients. While currently clinicians work towards identifying the most appropriate DSM diagnosis or diagnoses for each client to guide treatment, it may require few extra resources to obtain more extensive detailed symptom level data, that can be used with statistical learning methods to cluster clients into groups with increased biological and clinical homogeneity. These cohorts can be followed in observational studies in outcomes effectiveness, and potentially be recruited to participate in biomarker studies. Additionally, in the age of the Internet, ascertaining self-report symptoms require few resources and can be done remotely.

In conclusion, this study provides novel findings indicating that self-report psychiatric symptoms may be used to identify clinically and biologically homogeneous psychiatric populations. These symptom data can be used when constructing a biologically valid taxonomy for psychiatry and will enhance the bi-directional translation of knowledge from the bench to the clinic through a common terminology. Continued work into feature selection and interpretation of results with these data will facilitate the construction of a psychiatric taxonomy that is biologically valid and translates to clinical psychiatric care.

Abstract

Bipolar Disorder (BD) is a chronic and disabling disease that usually appears around 20 to 30 years old. Patients who suffer with BD may struggle for years to achieve a correct diagnosis, and only 50% of them generally receive adequate treatment. In this work we apply a machine learning technique called Inductive Logic Programming (ILP) in order to model relapse and no-relapse patients in a first attempt in this area to improve diagnosis and optimize psychiatrists' time spent with patients. We use ILP because it is well suited for our multi-relational dataset and because a human can easily interpret the logical rules produced. Our classifiers can predict relapse cases with 92% Recall and no-relapse cases with 73% Recall. The rules and variable theories generated by ILP reproduce some findings from the scientific literature. The generated multi-relational models can be directly interpreted by clinicians and researchers, and also open space to research biological mechanisms and interventions.

Keywords:

Bipolar Disorder; Depression Relapse; Multi-relational Model; Inductive Logic Programming; Machine Learning.

Introduction

The Diagnostic and Statistical Manual of Mental Disorders (DSM), published by the American Psychiatric Association, organizes all psychiatric disorders and other problems into five different categories, or axes. Axis I disorders, the focus of this work, includes all psychological diagnostic categories such as depression, anxiety disorders, and bipolar disorder, among others, except mental retardation and personality disorders that fall into Axis II. A psychiatric disorder involving both manic and depressive episodes, Bipolar Disorder (BD), which falls into the Axis I category, is a chronic and disabling disease that usually appears around 20 to 30 years old. Patients who suffer with BD may endeavor for years to achieve a correct diagnosis, and only 50% of them generally receive adequate treatment. Commonly, the mood episodes lead to personal and professional problems, and due to the disease's progression character, the euthymic periods (without mood episodes) become gradually shorter [1]. A WHO study [2] evidenced the devastating impact of BD: all around the world, approximately 29.5 million people present BD, which occupies the 12th position relative to the major causes of moderate to severe incapacity. With 22.2 million people in such conditions, this study also reveals that 2.5% of the years of incapacity are related to BD episodes. Relapse prevention is the main target in BD treatment, since the relapse rate is around 50% at one year and 70% at four years treatment [1, 3, 4].

Due to this alarming picture, a number of researchers started to explore the aspects underlying the BD outcome, in particular, genetic, neurobiological, environmental and phenomenological factors, as well as the interactions between them. As BD presents multi-factorial and multidimensional characteristics, there appears to be an urgent necessity of new techniques to investigate patterns associated with the course of this disease, especially the computational and mathematical ones. Machine learning and data mining bring the possibility of new hypotheses discovery through the exploration of datasets (new or not), neuroimaging and biomarkers, thus opening space to the research of new biological mechanisms and interventions [5, 6].

In fact, machine learning have been already applied to the study of BD. Mourão-Miranda *et al*. [7] have applied Gaussian Process Classifiers (GPC), a machine learning approach that assigns a predictive probability of group membership to an individual person, to differentiate groups and to identify those at-risk adolescents most likely to develop future Axis I disorders. The work was done collecting information from functional magnetic resonance imaging after the teens performed two emotional face gender-labeling tasks (happy/neutral; fearful/neutral). Using GPC, neural activity to neutral faces presented during the happy/neutral experiment accurately and significantly differentiated groups, achieving 75% accuracy (sensitivity=75%, specificity=75%). More recently, Schnack *et al*. [8] used Support Vector Machines (SVM) to distinguish among three groups of patients. They scanned 66 schizophrenia patients, 66 patients with bipolar disorder and 66 healthy subjects on a 1.5 Tesla magnetic resonance imaging scanner. Three SVM were trained to separate patients with schizophrenia from healthy subjects, patients with schizophrenia from those with bipolar disorder, and patients with bipolar disorder from healthy subjects, respectively, based on their gray matter density images. The predictive power of the models was tested using cross-validation and in an independent validation set of 46 schizophrenia patients, 47 patients with bipolar disorder and 43 healthy subjects scanned on a 3 Tesla magnetic resonance imaging scanner. Schizophrenia patients could be separated from healthy subjects with an average accuracy of 90%. Additionally, schizophrenia patients and patients with bipolar disorder could be distinguished with an average accuracy of 88%. The model delineating bipolar patients from healthy subjects was less accurate, correctly classifying 67% of the healthy subjects and only 53% of the patients with bipolar disorder. In the latter group, lithium and antipsychotics use had no influence on the classification results. Application of the 1.5 Tesla models on the 3 Tesla validation set yielded average classification accuracies of 76% (healthy vs schizophrenia), 66% (bipolar vs schizophrenia) and 61% (healthy vs bipolar). Most of these works are based on image data. As far as we know, no work has been done on data col-

lected from clinical assessments such as demographic and bipolar disorder features collected from forms and from medical consultations.

In this work, besides working only with annotated clinical data, we also employ a non-propositional machine learning technique, Inductive Logic Programming (ILP), which combines inductive machine learning and logic programming [9]. Compared to other machine learning algorithms, an advantage of ILP is its use of relational logic as a representation language. Learning systems that use this kind of representative language are known as Relational Learning Systems (RLS). In this approach, objects are structurally described, i.e., according to their components and relationships between them. The employment of relational logic as a representative language allows the induction of predicates. As a consequence, the number of concepts that can be learned is expanded. RLS are highly expressive for representing concepts and are able to represent the domain knowledge in such a way that is directly intelligible for people – a fundamental characteristic whenever one aims to extract knowledge from a given domain [10].

In this study, we investigate the use of ILP to generate a multi-relational model for studies of depression relapse in patients with BD. Our study considers demographic and clinical features, organized in multiple tables, which makes the dataset suitable for relational learning [11]. We generate interpretable classifiers, based on first-order logic, that capture the correlation between features included in this study to find patterns of relapse and no-relapse in patients with BD.

Methods

We explored data from a cohort of 139 patients with BD, followed by periods of 6 months to 10 years, from the Bipolar Disorder Program from the Institute of Psychiatry of São Paulo State University outpatient clinic. These data are associated with 102 variables covering psychiatric and medical comorbidity and history of BD, and 109 variables collected during the patient follow-up including medication and symptoms of mood. All participants in the study signed a consent form approved by the Ethics Committee for Research Project Analysis at the Hospital das Clínicas, Faculty of Medicine, University of São Paulo for use of data collected during the follow-up in clinical research.

Initially we identified patients who had continuous periods of remission until depression relapse, or that remained in remission. For this study, we considered only the first depressive relapse of patients. A broader definition of a relapse included both syndromal episodes and subsyndromal clinical states, because reports in the prior literature indicate an association between subsyndromal clinical status of BD and worse clinical and functional outcomes [1, 12, 13]. After filtering, we had 108 patients, where 86 (79.6%) cases are of relapse and 22 (22.7%) are of not relapse, which is representative of the reality of BD patients' outcomes [1 ,3, 4], especially in a university outpatient clinic that treats patients with more severe disorders. All clinical data and follow-up data of the patients were used to generate the relational models. We consider cut-offs of 4 weeks for remission time and classification of mood states based on Hamilton Depression Rating Scale and Young Mania Rating Scale as defined by the International Society of Bipolar Disorder [14, 15, 16].

ILP allows the expert's knowledge to be encoded as background knowledge. We use this characteristic to create predicates that allow searching for relationships between visits of patients. Thus, the ILP system is capable of exploring rules seeking patterns between several visits of the same patient including baseline visit, previous visit to relapse and relapse visit.

Unlike most machine learning approaches, ILP treats its positive and negative training asymmetrically, focusing on inducing rules that match many positive examples and few (ideally zero) negative examples. In this study, we investigate the potential of ILP in two tasks: automatically finding rules that correlate features of (1) relapse and (2) no-relapse cases.

We used Aleph (A Learning Engine for Proposing Hypotheses) [17], an ILP system completely written in Prolog, that was developed at Oxford University. Aleph receives as input: the background knowledge (BK) specified as a logic program; the hypotheses specification (H); an optional set of restrictions (I) relative to acceptable hypotheses; and a finite set of examples $E = E^+ \cup E^-$, where E^+ consists of a "positive" set of examples and E^- a "negative" set of examples. Aleph searches for a hypothesis H, relative to the restrictions I, so that H implies all examples in E^+ and none in E^-. In other words, H is true for all examples in E^+, but it is false for every element of E^-. As a default mode, Aleph applies a covering procedure that constructs a hypothesis through the generation of rules, one by one, using the positive examples. The final outcome consists of a collection of rules (clauses) represented in First Order Logic, known as a theory.

Aleph has several parameters that can be set to guide the search for better rules. We changed the default values of four of these parameters:

clauselength: sets the upper bound on number of literals in an acceptable clause

minpos: sets the minimum number of positive examples that a rule is required to cover.

noise: sets the maximum number of negative examples that a rule is allowed to cover.

nodes: sets the upper bound on the nodes to be explored when searching for an acceptable clause.

We chose 10 for *clauselength* to get rules with the largest number of features and related visits of a patient. We chose 2 for *minpos* in order to produce rules that generalize beyond a single case in the training set at minimum. For *noise* we chose 0, disallowing any rules that misclassify even a single positive example in the training set. Due to the large number of variables, we set the maximum number of *nodes* as 2,000,000.

In our experiments, we use stratified 10-fold cross-validation for evaluating the results. We used the same folds in both experiments (relapse and no-relapse). Metrics presented are collected across all folds, and are related to the test sets. For each experiment, we report the contingency table (TP: True Positives, FN: False Negatives, FP: False Positives and TN: True Negatives), Accuracy (Acc), Recall (Rec), Precision (Prec) and Specificity (Spec). Recall gives the true positive rate, Precision gives the rate of correctly classified positives and Specificity gives the true negative rate.

A statistical analysis of the variables was performed. Sociodemographic and psychiatric characteristics at baseline were compared between relapse and no-relapse groups using the chi-square test for categorical variables (Fisher's exact test if cell counts expected <5), the Student's t-test for normally distributed continuous variables, and the Wilcoxon Mann-Whitney test for non-normally distributed continuous variables. Analyses were conducted using SPSS (V.15.0). All statistical analyses were conducted using a two-sided significance level of α=0.05.

Results

Socio-Demographic and Bipolar Disorder features

In the overall sample, mean age was 40.2 years old (sd. 11.5), ranging from 22 to 76; 72 (66.7%) were female, 84 (77.8%) were Caucasian, 47 (43.5%) were single and 41 (38.0%) married, 16 (14.8%) divorced and 4 (3.7%) widowed, the mean years of education was 11.78 (sd. 3.25) ranging from 3 to 18. The majority of patients, 99 (91.7%), was diagnosed with BD I. Of the 108 subjects evaluated, 86 (79.6%) had a depressive episode relapse. Table 1 shows socio-demographic and BD comparison between groups. No difference was observed regarding the medication in use at baseline: lithium - relapse group (RG) n=29, 33.7% vs. no-relapse group (NRG) n=9, 40.7%, (p=0.53); anticonvulsant - RG n=51, 59.3% vs. NRG n=12, 54.5%, (p=0.69); second generation antipsychotics - RG n=32, 37.2% vs. NRG n=7, 31.8%, (p=0.64); first generation antipsychotics - RG n=3, 4.7% vs. NRG n=0, 0.0%, (p=0.58); antidepressants - RG n=27, 25.0% vs. NRG n=2, 9.1%, (p=0.06).

Table 1– Socio-demographic and Bipolar Disorder characteristics in Relapse and No-Relapse Group

	Relapse	No-relapse	p
n (%)	86 (79.6%)	22 (20.4%)	
Female (n, %)	60 (69.8%)	12 (54.5%)	0.18
Age (mean, sd)	40.9 (12.0)	37.6 (8.9)	0.23
Years of education (mean, sd)	11.8 (3.3)	11.8 (3.0)	0.97
Caucasian (n, %)	69 (80.2%)	15 (68.2%)	0.19
Bipolar Disorder (n, %)	Type I 78 (90.7%) Type II 8 (9.3%)	Type I 21 (95.5%) Type II 1 (4.5%)	0.47
Presence of psychotic symptoms (n, %)	52 (60.5%)	12 (54.5%)	0.53
Age of BD onset (median, iqr)	18.5 (15.0-26.0)	27.0 (17.0-32.0)	0.03
Years with BD (median, iqr)	15.5 (10.0-23.8)	10.0 (6.0-16.0)	0.01
Rapid cycler (n,%)	8 (9.3%)	1 (4.5%)	0.49
Psychiatric comorbidity (n, %)	52 (60.5%)	13 (59.1%)	0.91
Suicide attempt	21 (24.4%)	5 (22.7%)	0.87

Multi-Relational Model

The theories obtained by Aleph were translated from first-order logic to English to make them easier to read. The theory derived for relapse (RG) was composed by four rules and the one derived for no-relapse (NRG) by two rules, which are described next.

Relapse (RG) theory

1. The patient did not have a binge eating disorder, did not have insomnia in the middle of the night in the visit before the relapse, did not have psychotic symptoms and has not been using hypnotic medication.
2. The patient presented loss of interest in activities (hobbies or work), indecision and vacillation in the relapse visit.
3. The patient was not a rapid cycler, was using two different medications, one of them was an anticonvulsant, and at the baseline visit he/she did not have insomnia in the middle of the night and suicidal thoughts.
4. The patient had the BD onset before 17 years old, and did not meet criteria for alcohol abuse lifetime, and at the relapse visit complained about subjective tension and irritability.

No-Relapse (NRG) theory

5. The patient did not present a depressed mood (sadness, hopeless, helpless, worthless) and somatic symptoms.
6. The patient had 13-17 years of education.

The quantitative results from 10-fold cross-validation for each experiment are presented in Table 2. Metrics presented are collected across all folds and are related to the test sets.

Table 2– Accuracy performance

	TP	FN	FP	TN	Acc	Rec	Prec	Spec
RG	79	7	9	13	0.85	0.92	0.90	0.59
NRG	16	6	4	82	0.91	0.73	0.80	0.95

Discussion

Aleph discovered several rules that confirm facts in the literature. Moreover, it discovered patterns that can predict in which conditions a new patient will have the next relapse occurrence, facilitating the immediate detection of the problem and suitable treatment.

As far as we know, this is the first study on the use of ILP to generate a multi-relational clinical model in BD. In addition, this is the first experiment in the major area of psychiatric disorders that explores machine learning classifiers to perform multi-correlation of patients' clinical features based on a longitudinal dataset. In a research area where the finding for interpretable and meaningful patterns is eagerly sought, ILP produced very good initial positive results. The generated rules selected clinical features associated with outcome in BD already described in the scientific literature. Moreover, the associations found by ILP are richer than the ones produced by the so-called black-box models. ILP also produces multivariate correlations as it can combine several variables in the same rule. As ILP is not based on numerical processing, we do not need to worry about missing values.

ILP Theories

BD patients have circadian rhythm genetic abnormalities making them especially sensitive to sleep changes [18]. Sleep disturbance in BD is associated with a more severe course of illness, presence of psychotic symptoms and use of anticonvulsants suicide attempts [19]. All these features were present in the relapse group rules. For example, Rule (1) and Rule (3) mention lack of insomnia, and Rule (3) correlates lack of insomnia and intake of anticonvulsants to a relapse. Anticonvulsants, especially valproic acid, valproate and divalproex are used as mood stabilizers in BD. Better rates of mood stabilization are observed when associated with lithium. When used in monotherapy, they are as effective as lithium [20]. Therefore it is expected that they have a strong role in relapse presence. Lamotrigine, another anticonvulsant with significant positive results in the treatment of BD [21] is included in this group. Anxiety and early age of BD onset are also associated with a poorer outcome [1, 22, 23], and included in Rule (4). BD is strongly associated with suicide. A review study about suicide and BD clinical samples described that between 14-59% of the patients have suicide ideation, 25-56% present at least one suicide attempt during their lifetime and 15-19% die from suicide [24]. Rule (3) is associated with rapid cycling, which was already observed in the literature. Moreover, the use of anticonvulsants in BD is also associated with impulsivity and irritability, both associated with suicide attempts.

Subsyndromal depressive symptoms are strongly associated with depressive relapse [13]. In all rules there is at least one depressive symptom. Interestingly, the rules also describe the absence of specific depressive symptoms as a predictor of depressive relapse. Rule (2) consists only of depressive symptoms. In the No-relapse theory, Rule (5) consists only of depressive symptoms, strengthening once more the power of subsyndromal role in depressive relapse. Rule (6) is associated with years of education. Education is associated with higher levels of resilience, the ability to cope with stress or adversity, which is positively associated with better outcomes [25].

A possible limitation concerning our sample is the difference of BD age onset and years with BD between groups. The early BD onset as a factor associated with relapse was observed in the statistical and ILP analyses. It is well known in the literature the negative impact of early age of onset in BD outcome [1]. Other limitations could be related to the follow-up and number of visits per subject, once they were naturalistically followed and the visits were scheduled according to mood changes. A structured follow-up program could reduce this bias in future machine learning studies.

ILP as a Classifier

Besides producing rules that can represent patient patterns and allowing for the representation of new background knowledge that can be incorporated in to the raw data, ILP rules can also work as classifiers that can predict relapse or no-relapse of future cases. Results in Table 2 show the expected performance of a classifier based on rules produced by Aleph on our dataset. As explained before, these results were generated using 10-fold cross-validation (which is a standard machine learning validation procedure) and results are reported for the test set.

The first row of Table 2 shows results for rules that can predict in which situation a patient will have a relapse. These rules are based on the four rules discussed in the Results section. This classifier has a very good accuracy of 85%, being able to correctly predict 92 out of the 108 patients. On the relapse class, it does quite well with a 92% Recall, meaning that it misclassifies only 7 patients that actually have a relapse. This has a very important clinical meaning, since psychiatrists can concentrate their attention on the most needed patients with a very regular follow-up, while scheduling other patients to a more spaced time interval. It is important to note that the current practice routine considers all patients as potential relapse cases.

The second row of Table 2 shows similar results, but from the point of view of the no-relapse patients. If we look at the error rate of this classifier, it can perform even better than the first classifier for relapse cases. In other words, if the classifier says that a case is no-relapse, only 4 actual relapse cases are misclassified, while most of the no-relapse cases (16 out of 22, 73%) are still correctly classified. This means that 73% of the actual no-relapse cases can have a different treatment and have less regular visits to the psychiatrist, again leaving more time for the psychiatrists to concentrate on the actual relapse cases.

These are very encouraging results which open a new path to novel discoveries in the area of mental disorders.

Conclusion

In this work, we use ILP to develop a multi-relational model that highlights patterns of relapse and non-relapse in patients with BD. The results confirm that ILP can generate accurate relational models. The models are easy to interpret, since they are based on a rule-based language helping the experts to better understand the found patterns. By using this language, the expert can also add new knowledge to the raw data. Rules pinpoint features that were already reported in the literature such as use of convulsants and cases of insomnia, among others, but more importantly, they correlate many variables, contrary to most studies in the literature that only find uni- or bivariate correlations.

We used 10-fold cross-validation on a set of 108 patients, 22 with no-relapse and 86 with relapse. Results show that we can achieve very good accuracy when predicting either class and very good Recall (up to 95% specificity on the no-relapse class), numbers that are better than the ones found in the literature so far.

Another advantage of ILP is that it can handle multiple tables, which is not so trivial with propositional methods that require that the data is represented in a flat table format. For example, in our experimental setting, each patient can have a variable number of visits per month (up to 45 non-consecutive visits in 125 months), and each visit is associated to several different characteristics (totaling 211 variables per patient). Generating a flat table for this kind of data keeping the absolute time of the visit would require a huge, sparse, and redundant table with 13,727 columns for each patient. In addition, models produced with the ILP learner would not be comparable with models produced with this flat table.

Some ILP limitations concern the rapid growth of the search space relative to database growth. Such situations may lead to a high computational cost for the rule construction, thus making it more difficult to find the best solution.

ILP and other approaches in machine learning could be especially useful in exploratory studies with a multifactorial approach, as translational research, and the possibility to find patterns with impressive precision. The mental disorder field could be explored as a tool to link neurobiology with clinical phenotype. More research in other areas of mental disorders must be done to fully uncover the ILP potential.

Abstract

Breast cancer is the second most common cancer in the world. Currently, there are no effective methods to prevent this disease. However, early diagnosis increases chances of remission. Breast thermography is an option to be considered in screening strategies. This paper proposes a new dynamic breast thermography analysis technique in order to identify patients at risk for breast cancer. Thermal signals from patients of the Antonio Pedro University Hospital (HUAP), available at the Mastology Database for Research with Infrared Image - DMR-IR were used to validate the study. First, each patient´s images are registered. Then, the breast region is divided into subregions of 3x3 pixels and the average temperature from each of these regions is observed in all images of the same patient. Features of the thermal signals of such subregions are calculated. Then, the k-means algorithm is applied over feature vectors building two clusters. Silhouette index, Davies-Bouldin index and Calinski-Harabasz index are applied to evaluate the clustering. The test results showed that the methodology presented in this paper is able to identify patients with breast cancer. Classification techniques have been applied on the index values and 90.90% hit rate has been achieved.

Keywords:

Breast cancer; Thermal signals; Clustering; Validity indexes; Classification.

Introduction

Breast cancer is the most common cancer among women worldwide. However, when diagnosed and treated in early stages, this cancer type has relatively good prognosis [1].

Screening is a strategy adopted by health authorities in order to identify women who are at initial stages of breast disease. Thus, it is necessary to develop methods and techniques in order to improve screening procedures because even mammography, which is considered the gold standard for cancer detection, has its limitations, such as high false positive classification rate, insufficient effectiveness in dense breasts and use of ionizing radiation to form breast images [2][3].

Since the cancerous tissue temperature is generally higher than healthy surrounding tissues, thermography has been considered a promising screening method for breast cancer detection by generating images that reveal the heat distribution on the breast surface [3].

The thermal signals used in this work originated from dynamic thermography, which is a method for monitoring the dynamic response of the skin temperature after thermal stimulus. In other methods for detecting breast cancer, the thermal stimulus most utilized is the application of air flow directed to the breasts by an electric fan [4][5][6]. The cooling of the breasts, theoretically, improves the thermal contrast between healthy and unhealthy tissues in the image, because blood vessels promoted by cancerous tumors do not have muscular layer and neural regulation like embryological vessels. These vessels are only endothelial tubes and therefore do not contract in response to sympathetic stimulation. For that reason breast region with cancerous tumors remain with unchanged temperature while the healthy part of the breast is cooled down [7].

When compared to static thermography, dynamic thermography is faster and more robust. Indeed, static thermography requires rigid environmental conditions and significantly long time for acclimatization of the patient to examining room conditions. On the other hand, dynamic thermography is much less dependent of the conditions and temperature of the examining room [8].

This paper proposes a new dynamic breast thermography analysis technique in order to identify patients at risk for breast cancer. Dynamic thermal signals from patients of the HUAP, available at the Mastology Database for Research with Infrared Image - DMR-IR [9] were used for validating this hypothesis. First, each patient has her images registered. Second, the breast region is divided into regions of 3x3 pixels and average temperature from each of these regions is observed in all images of the same patient. Features of the thermal signals of such regions are calculated. Then, the *k*-means algorithm is applied over the feature vectors building two clusters. Silhouette, Davies-Bouldin and Calinski-Harabasz indexes are applied to evaluate clustering. The test results demonstrated that the methodology presented in this paper is able to identify these patients. Classification techniques have been applied on the index values and 90.90% hit rate has been achieved.

The remainder of the paper is organized as follows: related work section contains main work identified in the literature; the methodology proposed in this work is detailed in the section of same name; in the section tests and results, results are presented and discussed; and the conclusion section concludes this paper and indicates future work.

Related work

In Gerasimova *et al.* [10], dynamic thermography has been performed in 46 histopathologically proven breast malignant and benign tumor cases before surgery. From regions with and without tumor, thermal signals have been generated and Fourier Analysis, Wavelet Transform and phase diagram have been applied in order to examine the behavior of these signals. The authors have concluded that chaotic phase diagrams correspond to the healthy tissue; while for cancerous tissues, irregular shape in phase space is typical. Furthermore, results indicate that for healthy tissue, the thermal signals are anti-

correlated, whereas in cancerous tissue, thermal noise correlation has been observed. According to these authors, these results indicate that abnormal tissue has no ability to adapt to external influences. In addition, according to the authors, the results are consistent to the golden rule in biomedical sciences. This rule states that healthy and normal biomedical systems are often very complex and that the complexity decreases when an abnormality or disease occurs.

In another work, Gerasimova *et al.* [3] have performed multifractal analysis over breast thermal signals produced by dynamic thermography to detect differences in behavior between tissue with malignant tumor and healthy tissue. The modulus maxima wavelet transform method has been applied to characterize the multifractal properties of the one-dimensional thermal signals of cancerous and healthy breasts. The authors have concluded that complex scalar multifractal properties of the signals over autonomic regulation are drastically altered when the disease is present. In such a study, both breasts of 9 women were imaged, 6 with cancer and 3 healthy. A photovoltaic detector camera *InSb* was used. During acquisition of the images, the patient remains seated with the arms down in order to avoid discomfort. Frontal images were captured at 1 meter distance in a controlled temperature environment between 20ºC to 22ºC. Each set contains 30,000 image frames acquired during 10 minutes. Skin surface markers were used as landmarks for image registration phase in order to eliminate motion artifacts and do not hinder the analysis. In sick patients, the tumor region and the symmetrically positioned region in the other breast are delimited by square regions of 8 x 8 pixels. The analysis has been performed only within these regions. The methodology is able to discriminate between healthy region and region with tumor. Healthy regions exhibited signals with multifractal dimension as complexity signature and tumor regions exhibited signs with monofractal dimension as evidence of loss of complexity.

Recently, Gerasimova *et al.* published another work [11] using a much larger database, with 33 patients with histopathologically proven cancer and 14 healthy volunteers for control. The findings reaffirm the results of the prior study [3].

Scully *et al.*[12] also conducted analysis of skin thermal signal in patients with skin cancer. The temperature monitoring was performed by dynamic thermography. 1,500 thermograms, containing the region with disease, were collected using a camera FLIR SC7700, during 25 minutes. The collected images have been registered in relation to the first image and Wavelet Transform was used to analyze the thermal signals. They found significant differences between the region of control and tumor regions.

Herman [8] claims that dynamic thermography is able to measure the difference in infrared emission between healthy tissue and melanoma during the temperature recovery process after removal from cold stress. Test results suggest that the temperature is higher in cancerous lesion than in non-cancerous lesion during the first 45-60 seconds of thermal recovery. In this methodology, the region with tumor is surrounded by a bounding rectangle. Then, a digital photograph and an infrared image are captured. The infrared image observes the situation of steady state under ambient conditions. After, the skin is cooled by cold airflow per 1 minute. Next, infrared images are captured during 200 seconds. The methodology was applied in 37 patients, 3 with histopathologically confirmed cancerous lesions. The method achieved 100% accuracy.

Liu *et al.* [13] used thermograms to observe the forearm temperature variation and perform classification between three tissues: with micro-vascularity, with large veins and no veins. 3,000 thermographs were captured during 12 minutes and were registered afterwards with reference to the first image of the sequence. Thermal signals of each pixel were built, totaling 81,000 signs. Clustering using *k*-means algorithm and *Short Time Series (STS)* distance were applied over the signs to identify tissues with similar behavior in time. The authors demonstrated differences between three tissue types in terms of temperature change over time (via temporal profiles), magnitude of frequency response (via FFT), and coherency (via wavelet phase coherence and power spectrum correlation).

Unlike previous work, our methodology applies machine learning to decide whether or not a given patient is at risk of breast cancer.

Methodology

Our methodology steps are: image registration; thermal signal construction; thermal signal feature extraction; clustering; clustering evaluation and classification model building.

Image Registration

During examination by dynamic thermography, the patient may perform involuntary movements from breathing and momentary imbalance. These movements cause differences from one image to another and consequently generate thermal noise in the formed signs. Figure 1 shows (a) the first image of a particular patient, (b) the seventeenth image of the same patient, and (c) the result of the subtraction of (b) and (a) images. It is possible to see the difference between the images by observing image (c) which illustrates the effect of the movement of the patient during the examination.

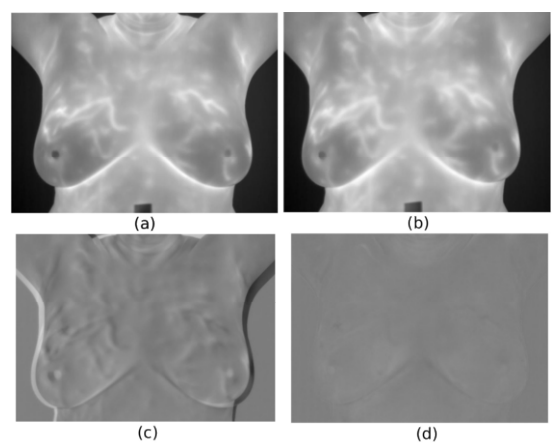

Figure 1- Image registration: (a) first image of sequence; (b) seventeenth image of sequence; (c) subtraction of (b) by (a) before registration; (d) the same subtraction after registration of these images.

In order to decrease the effects of these movements on thermal signals, registration of all images is performed. Registration is a process in which images, roughly speaking, are "matched". Considering two images (reference and sensitive) of the same scene, registration seeks to create a relationship between them to achieve the best overlap possible [14]. In this work, the first image of the sequence was considered the reference (immutable) image and the remaining images have been considered sensitive (transformable) images.

The registration is performed in two steps. In the first stage, a rigid body registration is applied based on intensities with geometric transformation consisting of translation, rotation, and scale. The second step uses non-rigid 2D registration with Residual Complexity (RC) [15].

The result of the registration can be seen in Figure 1(d). That image represents the subtraction of image (b) by image (a). After registration, the difference is much smaller than that one shown in image (c), before registration.

It is noteworthy that the data used in the analysis described in this paper are the temperature matrices of the breast surface, captured by an infrared camera. Thus the temperature matrix is converted to an image in gray tones, then the registration is performed in this image and the transformations are transferred back to the temperature matrix.

Thermal Signal Construction

After registration of the images, the formation of the thermal signal from the dynamic sequence of 20 images of a particular patient comprises the following steps:

1. The region of the breasts of the first image of the sequence is segmented creating a mask as shown in Figure 2(a);
2. The image region corresponding to the created mask is divided into a grid of 3x3 pixel squares R_k(Figure 2(b)), with k=1,...,p , where *p* is the amount of formed squares;
3. The averaged temperature of each square R_k is observed in all twenty images of the sequence producing the $S_k = (t_1,t_2,...,t_{20})$ thermal signal;
4. These twenty points are interpolated by cubic convolution yielding a signal of 1,901 points (in each interval between two points, 100 new points have been inserted, then 100x19 intervals = 1,900 + 1 (last point) = 1,901).

The S_k series values are ordered chronologically, *i.e.,* $t_1$is the mean temperature square R_k in the first image of the sequence, t_2 is the mean temperature square R_k in the second image of the sequence, and so on.

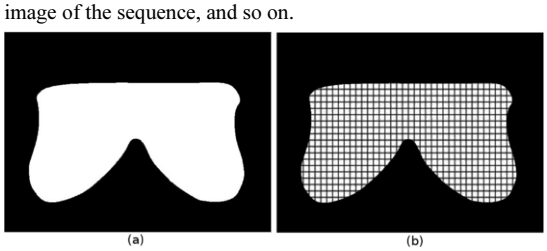

Figure 2 – Mask and grid of squares

Figure 3 shows the thermal signals of a sick patient and Figure 4 shows the thermal signals of a healthy patient. The *x*-axis represents time (the 20 points of each serie). The *y*-axis contains each of S_k (the index) of each thermal signal. The *z*-axis indicates the temperature in Celsius degrees. It can be seen that there is a group of thermal signals with higher temperature (red color) and with sharper increase in the early stages of the temperature recovery after thermal stress for the sick patient (Figure 3) however the same is not true for the healthy patient (Figure 4). The extracted features attempt to emphasize these differences.

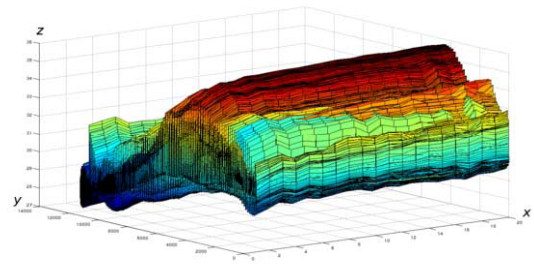

Figure 3 - Thermal signs of a sick patient.

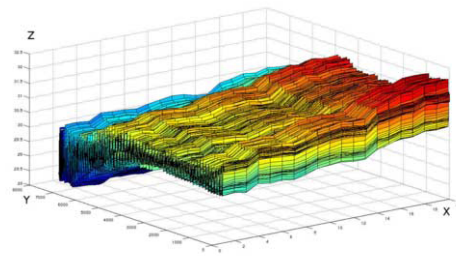

Figure 4 - Thermal signs of a healthy patient.

Thermal Signal Feature Extraction

The S_k time series can be treated as a biological signal of temperature t_i, i=1 ... N, where N=20. In biomedical systems, the evaluation of the complexity (main feature) is an important factor for diagnosis. This is possible through identifying and evaluating the complexity of the signal created by these systems [16].

In this work we used two signal complexity measures as features: the signal mobility which uses normalized first-order variations of the signal; and the signal complexity that uses second-order variations of the signal. The two characteristics measure the degree of variation along the signal. [16]. Considering a particular patient, from each sign t_i first-order variations are calculated, defined by d_i=t$_i$ − t_{i-1}, i=2 ... N, and second-order variations, defined by g_i=d$_i$ − d_{i-1}, i=3 ... N.

$$S_0 = \sqrt{\frac{\sum_{i=1}^{N} t_i^2}{N}} \quad (1)$$

$$S_1 = \sqrt{\frac{\sum_{i=2}^{N} d_i^2}{N-1}} \quad (2)$$

$$S_2 = \sqrt{\frac{\sum_{i=3}^{N} g_i^2}{N-2}} \quad (3)$$

Measures of complexity and mobility are defined in Equations (4) and (5), respectively:

$$C = \sqrt{\frac{S_2^2}{S_1^2} - \frac{S_1^2}{S_0^2}} \quad (4) \qquad M = \frac{S_1}{S_0} \quad (5)$$

Clustering, Evaluation of Clusters and Classification

The calculated features for each signal are stored in a vector. Clustering is performed over the set formed by feature vectors. In this work, we applied the *k*-means algorithm for clustering the vector set into two clusters. The two expected clusters are: thermal signals generated from diseased tissue and thermal signals generated from healthy tissue. We believe that for healthy patients the two clusters formed are very similar (healthy patients have no diseased tissues and, therefore, all the signs of both breasts are very similar), whereas for sick

patients the two clusters formed are more compact and well separated. The *k*-means algorithm has been performed by applying the correlation distance and three repeated steps, where each iteration has a different set of initial cluster centroid positions. The formed clusters are evaluated by clustering validity indexes. In this work, we applied: Silhouette index [17], Davies-Bouldin [18], Krzanowski-Lai index [19] and Calinski-Harabasz index [20].

The Silhouette index indicates the number of clusters that best separate the data set, *i.e.*, the maximum value of this index indicates the optimal number of compact and well separated clusters. It is defined by:

$$S(i) = \frac{b(i)-a(i)}{\max\{a(i),b(i)\}} \quad (6)$$

where $a_i$is the average dissimilarity (*i.e.* how far away two elements are from each other using, *e.g.*, Euclidean distance) of i with all other data within the same cluster, b_i is the lowest average dissimilarity of i to any other cluster of which i is not a member. Note that $-1 \ S \ 1$.

The Calinski-Harabasz index is defined in terms of the traces of the between-clusters and within-cluster scatter matrices. The trace is defined to be the sum of the elements on the main diagonal of the matrix. Calculated for each possible cluster solution, the maximal achieved index value indicates the best data clustering. It is calculated using the following equation:

$$\mathrm{CH}=\frac{[\mathrm{traceB}/K-1]}{[\mathrm{traceW}/N-k]} \text{for } \mathrm{K} \in \mathbb{N} \quad (7)$$

where B denotes the error sum of squares between different clusters (inter-cluster) and W the squared differences of all objects in a cluster from their respective cluster center (intra-cluster).

The Krzanowski-Lai is based on the square differences of all feature vectors in a cluster from their respective cluster center. It is calculated using the following equation:

$$\mathrm{KL}(K) = \left|\frac{\mathrm{DIFF}(K)}{\mathrm{DIFF(K+1)}}\right| \quad (8)$$

where

$$\mathrm{DIFF}(K) = (K-1)^{\frac{J}{2}} \cdot \mathrm{traceW}_{K-1} - K^{\frac{2}{J}} \cdot \mathrm{traceW}_K \quad (9)$$

which is the difference between a clustering in K and a clustering in $K-1$ clusters. J is the number of variables that have been measured on each $x_i \in X$and *trace* W_K the sum of square function that corresponds to the clustering in K clusters.

Regarding the Davies-Bouldin index, it requires the dispersion measure and the cluster similarity (how much the elements resemble each other) measure. Thus it is defined as the ratio of the dispersion within the clusters and the separation between clusters and is calculated by:

$$\mathrm{DB}(K) = \frac{1}{K}\sum_{\mathrm{k}=1}^{K} R_k \text{ ,K} \in \mathbb{N} \quad (10)$$

where

$$\left(\frac{S_k+S_J}{d_{\mathrm{k,j}}}\right), \ \mathrm{k} \in [1,\ldots,\mathrm{K}] \quad (11)$$

and

$$S_k = \frac{1}{\sum w_{\mathrm{k,i}}}\sum_{\mathrm{i}=1}^{n}\|x_i - \bar{x}_k\| \text{ ,k} \in [1,\ldots,\mathrm{K}] \quad (12)$$

as well as

$$d_{\mathrm{k,j}} = \left\|\bar{x}_k - \bar{x}_j\right\| \quad (13)$$

In the case of this index, the minimum observed value indicates the best solution for clustering.

Clustering validity index values have been used as features to generate classification models. These values have been submitted to Weka tool [22] applying the *MultilayerPerceptron* (a neural network), the BayesNet (a bayesian network), and the J48 (a decision tree) algorithms.

Tests and results

The used infrared images are from the *Mastology Database for Research with Infrared Image - DMR-IR*. This database is described by Silva *et al.* [9], where the image acquisition protocol is also described with more details. Briefly, in the execution of the protocol, regions of the breasts and armpits of the patient are cooled by an electric fan for some minutes in an environment with controlled temperature (20ºC to 22ºC). After cooling, 20 images are captured during 5 minutes. Images are captured using a FLIR thermal camera, model SC620 [21]. The sensitivity of the camera is smaller than 0.04ºC, the detectable temperature range is between -40ºC and 500ºC and images are generated with dimension of 640x480 pixels.

Tests have been performed with images of 22 patients including 11 with histopathologically proven cancer and 11 healthy. For each patient, all images obtained by dynamic thermography are submitted to the steps of the methodology described in the previous section and implemented in MatLab. The results are in Table 1, Table 2 and Table 3, respectively. In all tests, the *k*-Folds Cross Validation technique has been applied in order to evaluate the classification results, with *k=3*. In all tables, TP Rate is the true positive rate, FP is the false positive rate and AUC is the area under the ROC.

Table 1: Neural network classification result

Class	TP Rate	FP Rate	Precision	AUC
With cancer	0.81	0.00	1.00	1.00
Healthy	1.00	0.18	0.85	1.00
Weighted Avg	0.91	0.09	0.93	1.00

Confusion Matrix	Expected class	
	With cancer	Healthy
Classified as with cancer	9	2
Classified as healthy	0	11
Correctly Classified Instances	20	90.91%

Table 2: Bayesian network classification result

Class	TP Rate	FP Rate	Precision	AUC
With cancer	0.73	0.00	1.00	0.93
Healthy	1.00	0.27	0.79	0.93
Weighted Avg	0.86	0.14	0.89	0.93

Confusion Matrix	Expected class	
	With cancer	Healthy
Classified as with cancer	8	3
Classified as healthy	0	11
Correctly Classified Instances	19	86.36%

Table 3: Decision tree classification result

Class	TP Rate	FP Rate	Precision	AUC
With cancer	0.91	0.09	0.91	0.92
Healthy	0.91	0.09	0.91	0.92
Weighted Avg	0.91	0.09	0.91	0.92

Confusion Matrix	Expected class	
	With cancer	Healthy
Classified as with cancer	10	1
Classified as healthy	1	10
Correctly Classified Instances	20	90.91%

The percentage of correctly classified instances ranges from 86.36% to 91.90% considering the results of all classifiers. From the results obtained, we can conclude that the proposed methodology is potentially able to identify patients at risk for breast cancer. However, we will definitely confirm the effectiveness of the methodology when we extend our test database. At the moment, we are working hard to that effect.

Conclusion

Breast cancer has been killing many women around the world. This work has exploited the fact that breast regions with cancer produce thermal signals with complexity alteration when analyzed over time. Thermal signals have been generated by dynamic thermography. The complexity of these signals has been measured by well-known measures described in the literature. Then the *k*-means algorithm has been applied to the extracted features for clustering them into two clusters. Clustering validity indexes were applied to identify patients at risk for breast cancer. The test results demonstrated that the methodology presented in this paper is able to identify these patients. Classification techniques have been applied on the index values and 90.90% hit rate has been achieved. In future work, other features will be extracted as well as other clustering algorithms and clustering validity indexes will be tested.

Time-Series Data Analysis of Long-Term Home Blood Pressure Measurements in Relation to Lifestyle

Hiroshi Takeuchi, Naoki Kodama, Shingo Takahashi

Department of Healthcare Informatics, Takasaki University of Health and Welfare, Takasaki, Gunma, Japan

Abstract

We conducted a long-term time-series analysis of an individual's home blood pressure measurements, stored on a personal healthcare system in cloud, relative to the individual's lifestyle. In addition to daily scattering, apparent seasonal variations were observed in both systolic and diastolic blood pressure measurements. We examined the effect of seasonal variations on the outcome of a healthcare data mining process that extracts rules between blood pressure measurements and lifestyle components such as exercise and diet, and found that the daily blood pressure data approached a normal distribution when adjusted for the seasonal variations. This implies that an adjustment is desirable in order to produce appropriate rules in the healthcare data mining process.

Introduction

The mHealth and pHealth are currently the topics of great interest [1,2]. In particular, the demand for personalized healthcare systems to prevent diseases and improve health has been increasing [3]. Within this context, we have developed a personal dynamic healthcare system (PDHS) using cloud computing [4]. This system enables storage of the personal health and lifestyle time-series data in a database using a mobile device, and allows for the extraction of useful information, such as the rules and patterns of the lifestyles and health conditions contained within that data. We call this 'healthcare data mining.'

In the healthcare data mining process [5], we first check the correlation between variations of the time-series health data and summaries of the overall time-series lifestyle data. If the correlation coefficient is larger than a certain threshold, the lifestyle is selected as an independent variable in the data mining process relevant to the health condition. In this study, we analyzed the long-term time-series data of an individual's home blood pressure measurements in relation to his daily energy expenditure and supply (i.e. food-intake). Our specific focus is the effect of the seasonal variations in the home blood pressure measurements on the data mining process that extracts rules between blood pressure and energy expenditure/supply.

Materials and Methods

Subject and Method of Data Acquisition

The subject of this study was a 57-year-old (when the data storage began) male, who lives in Tokyo, Japan, and goes to the office on weekdays.

The blood pressure measurements (systolic and diastolic) were taken at home every morning upon waking, with an automatic blood pressure meter (Omron, Japan) using an oscillometric method. Each measurement was performed three times and the average value was then recorded. Energy expenditure due to exercise was measured with a wearable monitor (Omron, Japan) and the energy supply was estimated from each day's breakfast, lunch, and dinner contents. These data were entered via a mobile device and stored in a database using PDHS from 2004/06/01 to 2012/12/31.

Healthcare Data Mining Algorithm

Time-Delayed Correlation Analysis

The time-series data analysis described here is based on the simple idea that the accumulated effects of lifestyle, such as exercise and the diet, could affect personal health with some delay [5]. This delay may reflect complex bio-reactions such as those of the metabolism in a human body. In our analysis, the accumulation of lifestyle effects is represented by a summary of lifestyle data, namely energy supply and expenditure. The accumulated effects may cause corresponding variations in the vital signs (e.g. blood pressure), representing health conditions, with some delay. We call this 'time-delayed correlation analysis.'

In this analysis, we examine Pearson correlation coefficient, r, described as

$$r(\Delta h_{nm}, e^{t}_{ij}) = \frac{Cov(\Delta h_{nm}, e^{t}_{ij})}{SD(\Delta h_{nm}) SD(e^{t}_{ij})} \quad (1)$$

Here,

$$\Delta h_{nm} = h_n - h_m \quad (2)$$

is the difference between time-series health data h, representing the variation of the health condition, and

$$e^{t}_{ij} = e_i + e_{i-1} + ... + e_j \quad (3)$$

which is the summation of time-series lifestyle data e during a certain period, representing the accumulation of lifestyle effects. The delay is represented by retardation, $s = n - i \geq 1$ (**Figure 1**). In Eq. (1), $SD(\Delta h_{nm})$ and $SD(e^t_{ij})$ are the standard deviation of Δh_{nm} and e^t_{ij}, respectively, and $Cov(\Delta h_{nm}, e^t_{ij})$ is the covariance.

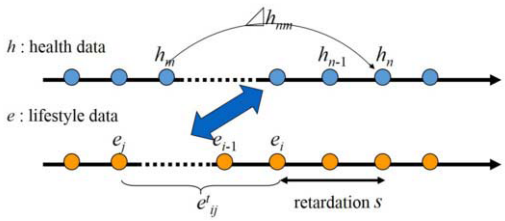

***Figure 1**: Time-delayed correlation analysis.*

Pearson correlation coefficient r is estimated for the time-series health and lifestyle data in a certain period by changing $n - m$, $i - j$, and s as parameters. If the maximum value of r is larger than a certain threshold, the lifestyle is selected as an independent variable in the data-mining process relevant to the health condition.

Rule Extraction

In the healthcare data mining process, the output (target) variable is a health condition. When the health data, h, are numeric, such as blood pressure measurements, time-series data are categorized into three classes, each representing a relative value: "higher," "moderate," or "lower." Threshold values used for this classification are determined so that the data frequency in each class is a similar number. In this study, rules are extracted with the decision tree algorithm C5.0. The study framework of time-delayed correlation analysis followed by the decision tree rule derivation is a novel approach.

Results

Time-Series Data of Blood Pressure

The time-series data of the daily systolic and diastolic home blood pressure measurements of the subject from 2004/06/01 to 2012/12/31 are shown in **Figure 2**. In addition to daily scattering, apparent seasonal variations were observed in both the systolic and diastolic blood pressure measurements. Blood pressure was higher in the winter than in the summer. Seasonal variation in the measurements has also been reported in relation to outside temperature [6].

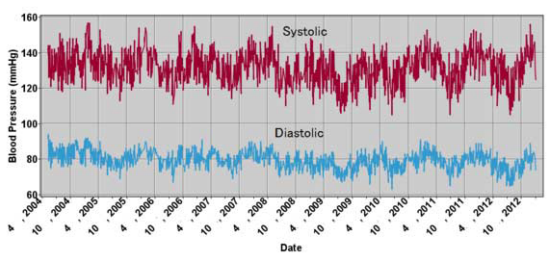

***Figure 2**: Time-series data of daily systolic and diastolic home blood pressure measurements of subject.*

To examine the seasonal variations in more detail, monthly average blood pressure values were plotted as shown in **Figure 3**.

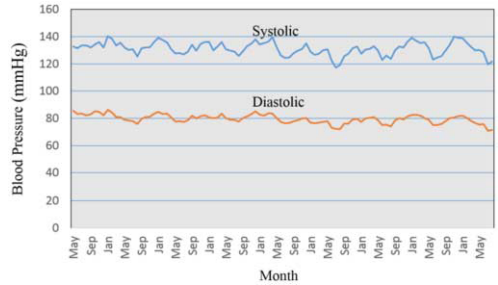

***Figure 3**: Monthly average systolic and diastolic home blood pressure measurements of subject.*

Adjustment of Seasonal Variation

We consider seasonal variation to create a bias in the correlation analysis between blood pressure and lifestyle, so we tried to adjust the blood pressure data based on the monthly average variation shown in **Figure 3**. The adjustment rate was changed monthly, as shown in Table 1.

***Table 1**: Adjustment rate of blood pressure data.*

Month	Adjustment Rate
1	0.97
2	0.98
3	0.99
4	1
5	1.01
6	1.02
7	1.03
8	1.02
9	1.01
10	1
11	0.99
12	0.98

Histograms of systolic blood pressure data before and after adjustment are shown in **Figure 4**.

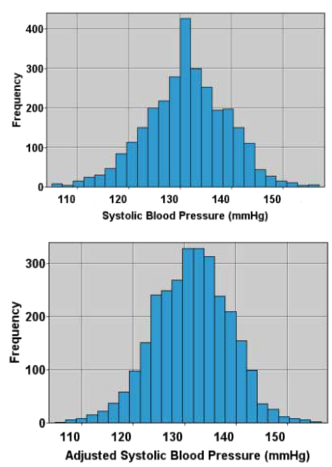

***Figure 4**: Histograms of systolic blood pressure data before and after adjustment.*

We found that the daily systolic blood pressure data approached a normal distribution when we adjusted for seasonal variations.

Histograms of diastolic blood pressure data before and after adjustment are shown in **Figure 5**. The diastolic blood pressure data also approached normal distribution after a seasonal adjustment. This implies that a seasonal adjustment is desirable to produce appropriate rules in healthcare data mining.

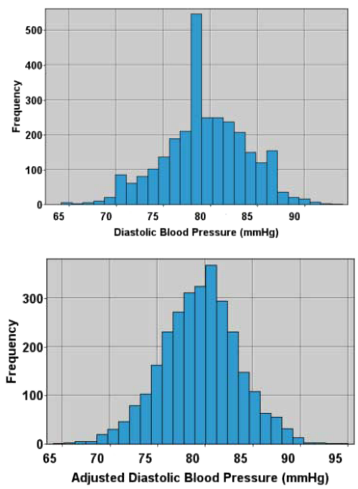

***Figure 5**: Histograms of diastolic blood pressure data before and after adjustment.*

Time-Delayed Correlation Analysis Using Adjusted Data

Time-delayed correlation analysis between blood pressure and energy expenditure/supply was performed using adjusted time-series data from 2004/06/01 to 2005/05/31 (the initial year). The parameter ranges in the analysis were $n - m = 1$–10, $i - j = 0$–9, and $s = 1$–3. Absolute values (magnitudes) of the correlation coefficients were largest when $n - m = 8$, $i - j = 1$, and $s = 1$ for the adjusted systolic blood pressure and energy expenditure/supply. Scatter plots of adjusted systolic blood pressure variation vs. energy expenditure and vs. energy supply under this condition are shown in **Figures 6** and **7**, respectively. Significant negative correlation to energy expenditure for two days and significant positive correlation to energy supply for two days were observed.

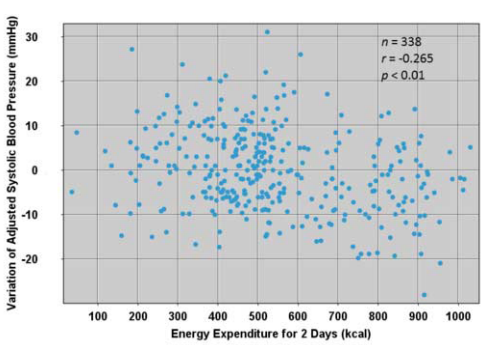

***Figure 6**: Scatter plots of adjusted systolic blood pressure variation vs. energy expenditure for two days.*

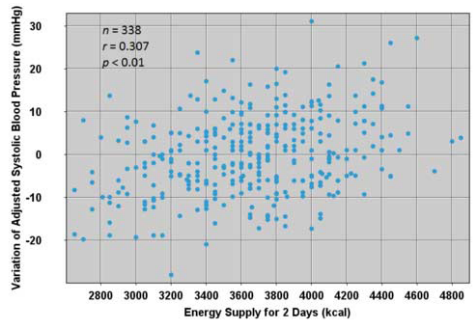

***Figure 7**: Scatter plots of adjusted systolic blood pressure variation vs. energy supply for two days.*

For comparison, the results of the time-delayed correlation analysis using non-adjusted time-series data during the same period are shown in **Figures 8** and **9**. Maximum correlation occurred when $n - m = 8$, $i - j = 1$, and $s = 1$ for both energy expenditure and supply. No significant difference was observed in the scatter plots before and after the adjustment.

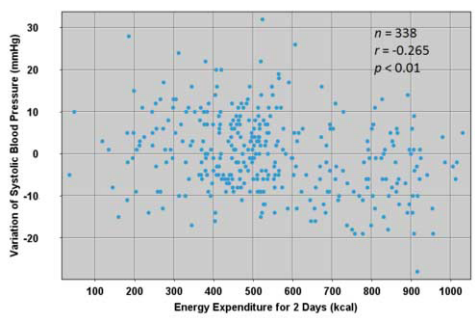

***Figure 8**: Scatter plots of systolic blood pressure variation before adjustment vs. energy expenditure for two days.*

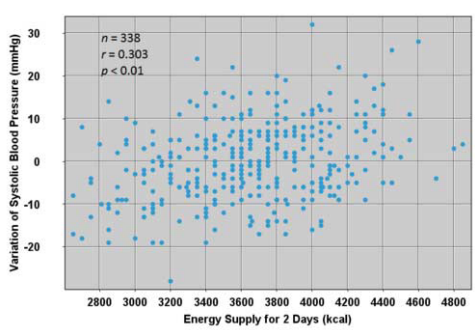

***Figure 9**: Scatter plots of systolic blood pressure variation before adjustment vs. energy supply for two days.*

This may stem from the fact that, in this analysis, periodic seasonal blood pressure variations were almost completely cancelled out by Eq. (2), since the parameter range was small ($n - m = 1$–10) compared to the period of seasonal variation. We therefore consider seasonal variation of blood pressure to have little effect on the time-delayed correlation analysis for selecting independent variables in the healthcare data mining process.

Rule Mining with C5.0 Algorithm

In the rule mining process, independent variables were energy expenditure and energy supply for two days, with a delay of one day with respect to the corresponding measurements of the blood pressure as explained in the previous section. The output (target) variable was the systolic blood pressure categorized into three classes each representing a relative value: "higher," "moderate," or "lower." Threshold values used for this classification were determined so that the data frequency in each class was similar. Rules were extracted on the basis of the time-series data from 2004/06/01 to 2005/05/31 (the initial year) using the C5.0 algorithm. An example of the decision tree for adjusted systolic blood pressure is shown in Figure 10.

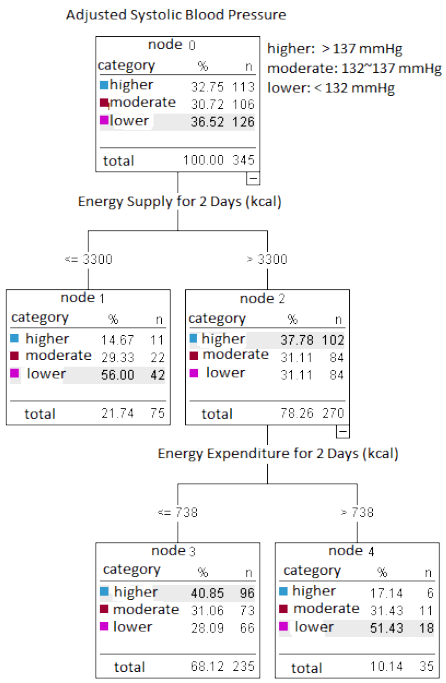

***Figure 10**: Decision tree for adjusted systolic blood pressure in relation to energy expenditure and supply.*

The decision tree produced the following rules:

1. If energy supply for two days is less than 3300 kcal, systolic blood pressure is lower (lift: 1.53).
2. If energy supply for two days is more than 3300 kcal and energy expenditure for two days is more than 738 kcal, systolic blood pressure is lower (lift: 1.41).

Here, '*lift*' is a measure of the performance of a targeting model at classifying cases. For comparison, an example of the decision tree for non-adjusted systolic blood pressure is shown in Figure 11. This decision tree produced a different rule:

3. If energy expenditure for two days is more than 570 kcal, systolic blood pressure is lower (lift: 1.43).

In general, a simpler model with fewer decision branches might be preferable. However, the rule with higher lift (1.53) involving energy supply as a lifestyle component is missing here. Thus, the adjustment of seasonal variations of blood pressure data seems to be effective at producing useful rules in healthcare data mining; although, it had little effect on the time-delayed correlation analysis to select independent variables.

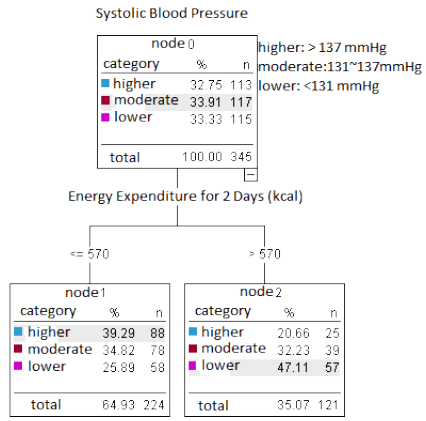

***Figure 11**: Decision tree for systolic blood pressure in relation to energy expenditure and supply.*

The adjustment of seasonal variation of blood pressure data affected the rule production. This is because the time-series blood pressure data were categorized into three classes with similar data frequency in each class for the rule mining process.

Discussion

Avoidance of Seasonal Variation Effect

Apparent seasonal variations were observed in the time-series data of an individual's home blood pressure measurements. The results of this study suggest that adjusting the seasonal variation is a desirable way to produce simpler rules between blood pressure and lifestyle (e.g. energy expenditure and supply). However, it is difficult to provide users of our PDHS with precise rules because the details of seasonal variations of personal data will only be recognized after storing the data for a long time, as shown in this study.

We tried to extract rules based on the time-series data of only three months (i.e. one season) to avoid any effect of seasonal variations. Figure 12 shows an example of the decision tree for non-adjusted systolic blood pressure based on data from 2004/06/01 to 2004/08/31 (summer in Japan). The form of the decision tree turned out to be the same as the one based on the adjusted time-series data of one year (Figure 10). Extracted rules were:

4. If energy supply for two days is less than 3700 kcal, systolic blood pressure is lower (lift: 1.29).
5. If energy supply for two days is more than 3700 kcal and energy expenditure for two days is more than 562 kcal, systolic blood pressure is lower (lift: 1.49).

These rules are similar to rules 1 and 2; although, the critical values for classification in the decision tree were somewhat different.

This result suggests that rule production based on the time-series data during only three months (one season) may be an

option for healthcare data mining. The extracted rules may still give enough information for adequate personal healthcare. At present, our PDHS produces rules once every three months for each user to avoid the effect of seasonal variations [7].

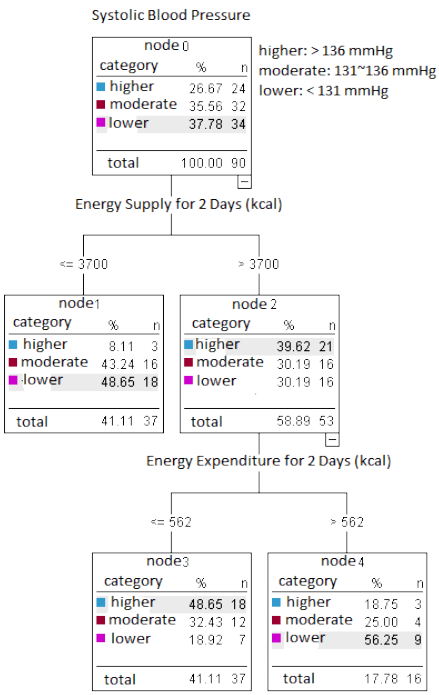

***Figure 12**: Decision tree for systolic blood pressure based on time-series data over three months.*

Threshold Values for Systolic Blood Pressure Classification

The aim of 'healthcare data mining' is to derive person-specific rules for health maintenance. In this study, the threshold values for systolic blood pressure classification were determined with a similar data frequency in each class (higher, moderate, or lower). However, the threshold values can also be determined to reflect a standard guideline in tems of defining the higher, moderate, and lower levels, unless the three classes have strongly skewed frequencies. The performance of a targeting model could be estimated by the 'lift' as well. In that case, the threshold values determined would be preferable in clinical use of our PDHS.

Summary

Long-term time-series data of an individual's home blood pressure measurements were analyzed to clarify the relation with lifestyle components, such as energy expenditure and supply. We found that the distribution of daily blood pressure data approached normal when the seasonal variation observed in the time-series data was adjusted, which demonstrates that an adjustment is desirable for producing appropriate rules between blood pressure and lifestyle components in the healthcare data mining process. The results of the healthcare data mining using the adjusted data are summarized as follows:

1. The adjustment of blood pressure data had little effect on the results of time-delayed correlation analysis to select independent variables in the data mining because, in this study, the parameter range of examining time-series correlation was small compared to the period of seasonal variation.
2. The adjustment of blood pressure data influenced the rule production process and different rules were extracted with the adjustment because the blood pressure data were categorized into three classes (higher, moderate, or lower) that were used for an output (target) variable.
3. Rules extracted after an adjustment were more useful for personal healthcare than rules extracted before the adjustment.
4. Rule production based on the time-series data of just three months (one season) is an option for healthcare data mining to avoid the effects of seasonal variation.

The Improvement of Dental Posture Using Personalized Biofeedback

Bhornsawan Thanathornwong[a], Siriwan Suebnukarn[b]

[a] *Faculty of Dentistry, Srinakarinwirot University, Bangkok, Thailand*
[b] *Faculty of Dentistry, Thammasat University, Pathumthani, Thailand*

Abstract

Background: Dentists are subject to staying in static or awkward postures for long periods due to their highly concentrated work. Objectives: This study describes a real-time personalized biofeedback system developed for dental posture training with the use of vibrotactile biofeedback. Methods: The real-time personalized biofeedback system was an integrated solution that comprised of two components: 1) a wearable device that contained an accelerometer sensor for measuring the tilt angle of the body (input) and provided real-time vibrotactile biofeedback (output); and 2) software for data capturing, processing, and personalized biofeedback generation. The implementation of real-time personalized vibrotactile feedback was computed using Hidden Markov Models (HMMs). For the test case, we calculated the probability and log-likelihood of the test movements under the Work related Musculoskeletal Disorders (WMSD) and non-WMSD HMMs. The vibrotactile biofeedback was provided to the user via a wearable device for a WMSD-predicted case. In the system evaluation, a randomized crossover trial was conducted to compare dental posture measure using tilt angles of the upper back and muscle activities of those dental students that received vibrotactile biofeedback from the system with the control group against the dental students who received no feedback. Results: The participants who received feedback from the system had a lower tilt angle at 10^{th}, 50^{th}, and 90^{th} percentiles of $Back_x$ and $Back_y$, as well as muscular load, which were statistically different ($p < 0.05$) from those who received no feedback from the system. Conclusions: The results presented here demonstrate that a personalized biofeedback system for posture training in dental students is feasible and associated with quantitative improvements of the dental posture.

Introduction

A large number of dentists suffer from musculoskeletal problems later in their professional lives. Some dentists have milder forms of musculoskeletal problems, while others have much more severe forms. A proportional correlation between the number of disorders and the years of clinical experience have been reported.[1] Dentists are subject to staying in static or awkward postures for long periods due to their highly concentrated work and the restriction of the oral cavity. According to Rising et al.,[2] more than 70 percent of dental students reported neck, shoulder, and lower back pain by their third year of dental school. In order to prevent this; correct dentist posture must be established early among dental students. Therefore, the correct posture must be stressed in dental schools. Although most schools teach the correct and ideal dentist posture and positions, they are not always applied by the dental students themselves.

A complex interplay of feedback and feed-forward control ensures the natural ability of the human body to maintain an upright stance, and to stabilize during movement.[3] One approach to improving balance which has been widely used in physical therapy and rehabilitation involves feeding back to the central nervous system supplementary environmental information about body motion. This supplemental information may come from a therapist, laboratory equipment, or artificial sensors.[4] Biofeedback (BF) systems for postural control are aimed at providing additional sensory information to supplement natural sensory information and improve human balance. Since the experimentation of biofeedback systems for postural control began, tactile and audio biofeedback have received much less attention than visual biofeedback. Nevertheless, in the last few years, interest in tactile- and audio-biofeedback systems for postural control has been renewed,[5,6] partially due to advances in technology for real-time processing and movement sensing, and to new trends in wireless wearable devices that can be worn during daily activities. Audio-biofeedback experimentation was carried out by Chiariet et al. [6] and Hegeman et al., [7] who developed audio BF devices able to encode trunk movement information into a sound. In 2001, Wall et al. [5] developed a device able to provide tactile feedback of trunk tilt by vibrating tactors that the subjects wore around their trunk. This study showed how vibrotactile feedback might improve balance performance in healthy subjects, as well as the possible usefulness and validity of this system as a prosthesis for people with pathologies that impair balance.

The use of biofeedback has been offered in the past as an instrument for training that enables an individual to learn how to change physiological activity or behavior for the purposes of improving performance. In therapeutic applications, biofeedback training of balance and posture has shown to be effective for posture control in adolescent scoliosis,[8] and has also decreased the fall rate in elderly patients with peripheral neuropathy.[9] In patients with bilateral vestibular loss,[10] biofeedback training was also found useful in enhancing postural stability even under challenging standing conditions, beyond the effect of practice alone.[10-12]

The aims of this study were to investigate the manner and tasks in which the personalized biofeedback system can be used to enhance postural control in dental operation, to explore the feasibility of using a personalized biofeedback system for posture training of dental students, and to preliminarily assess the usability and efficacy of a personalized biofeedback paradigm on a group of dental students. This study describes a real-time personalized biofeedback system developed for posture training with the use of vibrotactile biofeedback. The value of this study is that

no previous studies have shown how a personalized biofeedback system could be employed by dental students for monitoring their posture, as well as helping them to self-correct their posture and movements in order to minimize the risk of acquiring musculoskeletal problems. Although our focus of attention is in the area of dentistry, the proposed system could be applied to other domains that require self-monitoring and correction of posture.

Methods

Real-time personalized biofeedback system

The real-time personalized biofeedback system was an integrated solution comprised of two components (Figure 1): 1) A wearable device that contained an accelerometer sensor for measuring the tilt angle of the body (input) and provided real-time vibrotactile biofeedback (output). The angles to be measured included: flexion and extension, left and right lateral flexion during the operation. The system took those angles as input to the software. 2) The software was used for tilt angle data capturing, data processing, and personalized biofeedback generation. The implementation of real-time personalized vibrotactile feedback was computed using Hidden Markov Models (HMMs).[13] HMMs were used to predict whether the dental student was likely to acquire Work-related Musculoskeletal Disorders (WMSD) by comparing the dental student's movement patterns with WMSD and non-WMSD HMMs learned from previous data. The vibrotactile biofeedback was provided to the user via a wearable device for a WMSD-predicted case. The idea was to encourage dental students to correct upper back movement themselves after receiving vibrotactile biofeedback during their dental work.

Device

The wearable device developed by our group consisted of an electronic system that produced a voltage signal in reaction to body movements. It consisted of an ADXL345 3-axis accelerometer with high-resolution (13-bit) measurement at up to ±16g and a 12.5-400Hz bandwidth response. An accelerometer sensor was used for tracking body tilt angles. The accelerometer sensor presented two reading outputs, one for the X_{out} and another for Y_{out}, and a power supply voltage input of 2.0-3.6V. The expected values for X_{out} and Y_{out} were in the digital IO voltage range of 1.8-2.5V. The sensor consisted of a structure with a capacitive sensing cell (g-cell) and signal conditioning to detect small displacements. The signals from the accelerometer sensors were amplified and converted into digital signals through a data acquisition card (13-bit resolution) connected to a computer (Laptop computer with a Core i5 processor, running Microsoft® Windows 7). The accelerometer mounted on a circuit card was used as an inclinometer to calculate body tilt angles during the dental operation (Figure 2).

Software

The software was developed using Visual Studio to control and process the arrival of the signals obtained through a flash memory to the computer. The software configured the entrance channels and was programmed considering the pins where the sensors had been connected to the data acquisition card through an analogical signal interface cable. As soon as the signals arrived at the acquisition card, they were available in their respective channels. The voltages were used with calibration values in order to obtain the values of flexion/extension of the body tilt in degrees. Results from the data processing were stored in a database.

Figure 1 - Personalized biofeedback system

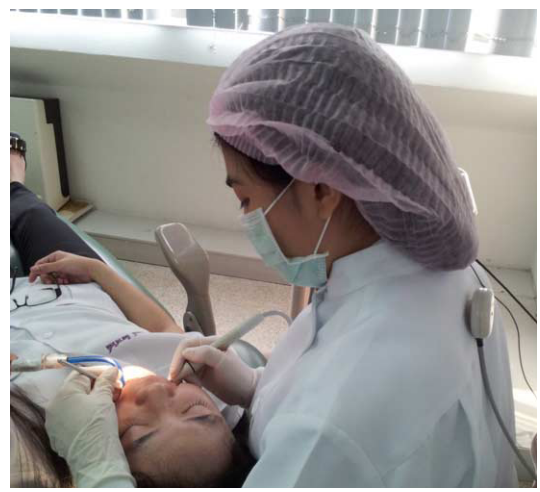

Figure 2 - The wearable device containing an accelerometer sensor and vibrotactile biofeedback module was attached to the operator's gown to measure the tilt angles of the upper back. The device was lightweight and did not interfere with the dental operation.

Personalized biofeedback

We propose a HMM as a statistical tool to objectively assess dental posture based on the measured data about the operator's tilt angles. HMMs have been used extensively, and have shown to be effective in applications such as gesture recognition [14] and speech recognition.[13] They also have been used for modeling human operator skills and transferring them to robots.[15] Recently, HMMs have been applied to model complex tasks such as surgery (specifically in automatic assessment of surgical performance in laparoscopy),[16] pelvic examination,[17] and mastoidectomy.[18] These applications suggest that HMMs have high potential to provide accurate models for assessing dental posture.

We conducted an experiment to test the ability of a machine learning technique, the HMM, to recognize and classify an observed dentist movement patterns as WMSD or non-WMSD, based on a set of recorded important features. The training data were obtained from fifty general dentists. Thirty

dentists were identified as WMSD, and 20 as non-WMSD according to Kroemer's guidelines.[19] Kroemer's guidelines classified WMSD into 3 stages: Stage 1 is characterized by local aches and tiredness during the working hour, which usually abate overnight and with days away from work; Stage 2 has symptoms of tenderness, swelling, numbness and pain that starts early in the work shift and does not abate overnight; Stage 3 is characterized by symptoms that persist at rest and during the night. In our study Stage 2 and 3 were considered to be in the WMSD group and Stage 1 or no symptoms were considered to be in the non-WMSD group. Informed consent was provided upon recruitment to the study. The operation selected for our study was scaling on the upper right quadrant of mild gingivitis patients during their routine schedule. During the work, we continuously stored the data on the right and left lateral flexion, and flexion and extension of the upper back ($Back_x$ and $Back_y$).

Once the models were trained, we calculated the probability and log-likelihood of the test movements under the WMSD and non-WMSD HMMs using the forward algorithm as described previously to find the model that best describes the test movement data. If the log-likelihood of the test movements under WMSD HMM was greater than under the non-WMSD HMMs, the system classified the test movement as WMSD; otherwise, it was classified as non-WMSD. The personalized vibrotactile biofeedback was provided to the user via a wearable device for a WMSD predicted case.

We used discrete HMMs to model the system. To validate the model precision, we performed five-fold cross validation. A different *k*-means clustering algorithm was used for every cross validation fold and the same *k*-means for the WMSD and non-WMSD model in the same fold. For each fold, we trained the WMSD HMM with four WMSD and four non-WMSD sequences. To determine the accuracy of the method, after training the two HMMs in each fold, we fed the test WMSD and non-WMSD data to each model. The average log likelihood of all sequences across all five folds for the two HMMs is shown in Table 1. In every cross validation fold, the log likelihood of every test sequence under its corresponding HMM was higher than that under the other HMM. These results demonstrate the ability of the HMM to distinguish between WMSD and non-WMSD movement with 100% accuracy.

Table 1 - Average log likelihood results for WMSD and non-WMSD movement sequences

	Log likelihood for WMSD HMM	Log likelihood for non-WMSD HMM
WMSD	-3.475×10^3	-2.121×10^6
Non-WMSD	-6.142×10^5	-3.584×10^3

System evaluation

Participants and design

In this study, a randomized crossover trial was conducted to compare tilt angles of the upper back and muscle activities of the participants that received vibrotactile biofeedback from the system with the control group who received no feedback. Upper back tilt angles while performing scaling on upper 1st and 2nd molars were measured. We hypothesized that the participants that received vibrotactile biofeedback from the system will improve their postures (decreased $Back_x$ degree and $Back_y$ degree, and upper trapezius muscle activity). We recruited sixteen dental students (8 females and 8 males) aged between 21 and 23. The choice of at least 16 participants per group was based on a 2-tailed test, with $\alpha = 0.05$ and power $(1-\beta) = 0.80$. The inclusion criteria were that the participants performed a minimum of 6 h of dental practice a day. They were not admitted to the study if they received below 70 percent marks in knowledge assessment of dental ergonomics. Participants answered a questionnaire about their health and workplace. None of them were excluded from the group on health grounds. The study was approved by the institutional Ethical Review Board. A written consent form was provided by all participants. Participants were randomly assigned into a 2x2 crossover trial using a computer–generated randomization schedule to each of two sequences of working. Participants in the experiment group received vibrotactile biofeedback from the system after finishing scaling (Feedback), while those who were in the control group received no feedback (Control).

Data analysis

The primary outcome measures were the mean values of $Back_x$ degree and $Back_y$ degree. The secondary outcome measure was upper trapezius muscle activity measured using electromyography (EMG). The primary and secondary outcome measures were recorded two times: after finishing scaling on the 1st molar (Pre-test) and finishing scaling on the 2nd molar (Post-test). The primary outcome measures were the angle in degree at 10th, 50th, and 90th percentile of $Back_x$ and $Back_y$ accurate to 0.01 degree. The secondary outcome measures were raw EMG signals processed with BioPAK™ Program software V 7.2 (BioResearch Associates Inc., RI, USA). Raw EMG data was transformed into frequency domain and band-pass filtered at a high-pass frequency of 10 Hz and a low-pass frequency of 500 Hz. Then, the data was inverse-transformed to time domain for further analysis. Accordingly, filtered signals were full-wave rectified and averaged across data collection period.Descriptive statistics were used to evaluate the effects of real-time personalized biofeedback system. Average, standard deviations and percentile were extracted as well as the percent change of post-test from pre-test. Personalized biofeedback effects (control vs. feedback group) were evaluated using the Paired t-test and were assumed to be significant at $p < 0.05$ (two-side). All analyses were conducted with the statistical package for the Social Science version 21.0 (SPSS, Chicago, IL).

Results

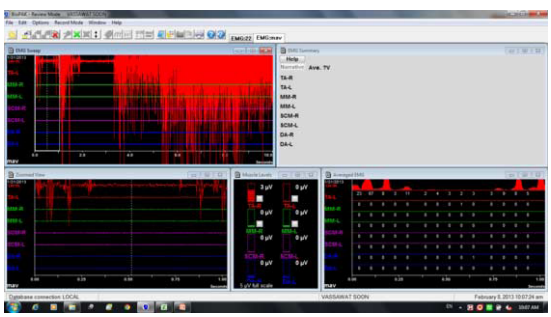
Dental students that received feedback from the system had lower tilt angles at 10th, 50th, 90th percentile of $Back_x$ and $Back_y$, as well as muscular load which were statistically different ($p < 0.05$) from those who received no feedback from the system. A significant improvement of 3.62-8.47 degrees was seen for forward movements, and 6.12-8.88 degrees for sideways movements in the group that received feedback. A sample EMG that shows muscular load for the right trapezius from one participant doing dental procedure is shown in Figure 3. There was lower muscular load for the right trapezius while receiving vibrotactile biofeedback from the system (Figure 3b), as compared to receiving no feedback (Figure 3a).

Discussion

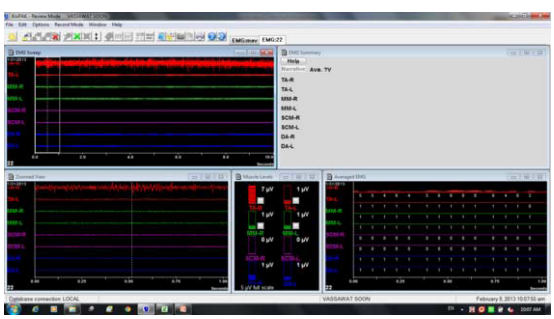
In a previous study, a real-time system with assistive feedback for postural control in rehabilitation found that the system was suitable for clinical applications pertaining to postural control improvements.[20] The limitations were that custom-developed software might not effectively be applied to all patients. Another study applied a wearable real-time

intelligent posture corrective system using vibrotactile feedback to improve ankle proprioception in wobble board training. A fuzzy inference system was used to determine the quality of postural control, based on inertial measurement units-acquired measurements of trunk and wobble board. The results observed an improvement in postural control with biofeedback intervention, demonstrating the success of the prototype built for improving postural control in rehabilitative and preventive applications.[21]

In our study besides posture position, the muscle activity was also assessed using EMG. During dental work there was higher load for the right trapezius in the control group, as compared to the feedback group. Our results are in line with the study on quantifying work load in neck, shoulders and wrists in female dentists.[22] It was found that dentists were exposed to high load on the trapezius muscles bilaterally, and steep, prolonged forward bending of the head.



(a)



(b)

Figure 3 - Relationships between muscular activity and maximal voluntary contraction (MVC) for right trapezius muscle of (a) control and (b) feedback from one participant. The upper-left window shows EMG sweep in 10 sec. of right trapezius muscle (read from TA-R electrode). The lower-left window is the zoomed view of EMG in 1 sec. The lower-middle window shows a single muscular activity level selected from the zoomed view. The lower-right window shows average EMG in 1 sec.

As hypothesized, the postural training using personalized biofeedback reduced muscle activity significantly. Trapezius muscle activity has been studied previously in dental work research due to the discomfort that is experienced in the neck/shoulder region.[22,23] The magnitude of EMG signals of the Trapezius muscles while working on the dental procedure were compared between sitting in the conventional chair and General Chair (Ergonomically Designed Chair EDC;) designed by strong support over the arms and trunk.[24] The results showed that the chairs are designed specifically to reduce activity of the muscles significantly and MVE% is close to the average value that is derived from data received participants' using personalized biofeedback in this study.

A study on biofeedback with muscle activity by Palmerud et al. [25] examined with electromyography in abducted arm positions. By using feedback techniques, they found that the subjects could reduce EMG activity voluntarily by 56% in the trapezius muscle while keeping different static postures. When compared with this study, the values of the EMG activity from a feedback group decrease by 53.15%. Thus, while you are working in the appropriate position, the function of the muscle decreases.

Many research experiments have been introduced using biofeedback information. Biofeedback systems have become a prominent component in motor training and rehabilitation. Alahakone et al. [20] found that instantaneous feedback provided via vibration stimulus can reduce postural sway based on trunk tilt measurements. Hence, the system's pertinence to comparable approaches employed in sports training and rehabilitation is apparent. Correspondingly, vibrotactile biofeedback improves gait in patients with unilateral vestibular loss. Results showed an immediate improvement in postural stability (reduction of lateral center of mass displacement, trunk tilt and medial-lateral step width), that was significantly larger than effects of practice alone.[26] In addition to evaluate the effectiveness of an audiobiofeedback system for improving balance in patients with bilateral vestibular loss. Audiobiofeedback improved stance stability of participants with bilateral vestibular loss by increasing the amount of postural corrections.[27]

To our knowledge, this is the first intervention trial using a personalized biofeedback system for training posture in dental students. The present study aimed to explore if this training method is feasible for dental students. Future studies should include a larger sample of dental students and dentists, as well as other occupations (e.g., surgeons, computer users, or drivers). Training with the personalized biofeedback system teaches participants new strategies of movement that could be applied to real-life situations. In this sense, the personalized biofeedback system may have an advantage over other technologies used by dentists, by enhancing motor learning through feedback on knowledge of performance, and knowledge of results. Further studies are needed to look at the possibility of using a personalized biofeedback system for daily training.

Conclusions

The results presented here demonstrate that the personalized biofeedback system for posture training in dental students is feasible, and associated with quantitative improvements of dental posture. This may be viewed as a promising first step to implement posture training strategies to minimize work-related musculoskeletal disorders in dentists and other healthcare workers.

Abstract

The manner in which people preferentially interact with others like themselves suggests that information about social connections may be useful in the surveillance of opinions for public health purposes. We examined if social connection information from tweets about human papillomavirus (HPV) vaccines could be used to train classifiers that identify anti-vaccine opinions. From 42,533 tweets posted between October 2013 and March 2014, 2,098 were sampled at random and two investigators independently identified anti-vaccine opinions. Machine learning methods were used to train classifiers using the first three months of data, including content (8,261 text fragments) and social connections (10,758 relationships). Connection-based classifiers performed similarly to content-based classifiers on the first three months of training data, and performed more consistently than content-based classifiers on test data from the subsequent three months. The most accurate classifier achieved an accuracy of 88.6% on the test data set, and used only social connection features. Information about how people are connected, rather than what they write, may be useful for improving public health surveillance methods on Twitter.

Keywords:
Machine learning; Social media; HPV vaccines; Public health surveillance; Twitter messaging; Text mining.

Introduction

Social media surveillance applications that provide value to public health include surveying demographics, estimating population-wide sentiment about public health issues like vaccines, forecasting influenza outbreaks, and producing spatial indicators of language, behaviour, and mood [1-7]. One of the specific problems associated with using Twitter for online surveillance is the brevity and non-standard text structures of Twitter posts (tweets), which limit the text fragments that can be used to train classifiers, and may limit performance [8, 9].

We hypothesized that connections between users on social media may help to improve surveillance methods for the following reasons: (a) homophily – where people tend to form connections with others who share similar attributes or opinions [10-12]; (b) contagion of opinions – where social connections represent the conduits through which information flows, influencing and shaping opinions [13-15]; and (c) temporal dynamics – where user relationships may change more slowly than the content in the topics being discussed.

To test the hypothesis that social connections could improve the performance of opinion classification methods, we considered a classification task in the surveillance of anti-vaccine rhetoric about human papillomavirus (HPV) vaccines on Twitter. The growth of anti-vaccine rhetoric in the media is an international problem [16, 17]. HPV vaccines are a relatively recent introduction to the armament of public health, and uptake is highly variable by country, demographic, and location [18]. Anti-vaccine rhetoric specifically directed at HPV vaccines is present in media articles and websites [19-21], and this appears to have the capacity to alter vaccine acceptance and decision-making [22].

The aim of this study was to determine if information about social connections could be used to improve the performance of classifiers intended for ongoing use in public health surveillance, using anti-vaccine rhetoric as an example.

Methods

Study Data

English-language tweets (42,533 tweets) containing keywords related to HPV vaccines were collected between October 1, 2013 and March 31, 2014. We identified these tweets by searching for combinations of keywords (HPV, vaccine, Gardasil, Cervarix, vaccination, cervical, cancer) via repeated calls to the Twitter application programming interface (API), in accordance with the terms of service for Twitter developers. For each of the users responsible for the tweets (21,166 users), the sets of users they followed (*sources*), as well as the sets of users that followed them (*followers*), were accessed through separate API requests and recorded soon after the first time they tweeted about HPV vaccines in the six-month period.

We split the six months of data into two distinct but contiguous three-month periods and randomly sampled tweets for use in the classifier training (1050 tweets from October 2013 to December 2013) and testing (1100 tweets from January 2014 to March 2014). Two investigators (DA and AD) independently rated each tweet as having presented an anti-vaccine opinion or otherwise. Agreement between the investigators was 95% in the training period (Cohen's kappa 0.88; $p<0.001$), and 95% in the testing period (Cohen's kappa 0.86; $p<0.001$). Disagreements were resolved by discussion. Tweets were removed if they were deleted or the user had become protected or suspended, or if the text was identical after pre-processing. Final samples used included 884 and 907 tweets in the training and testing period, of which 247 (28%) and 201 (22%) were labelled as anti-vaccine, respectively.

Data pre-processing

We pre-processed the text (content) to remove punctuation, words that were unlikely to confer meaning (e.g. 'and'), and other non-word elements (e.g. URLs). The remaining text was used to produce sets of unigrams (one word) and bigrams (two contiguous words), which were then available for use in the classifier training. An example is given in Figure 1.

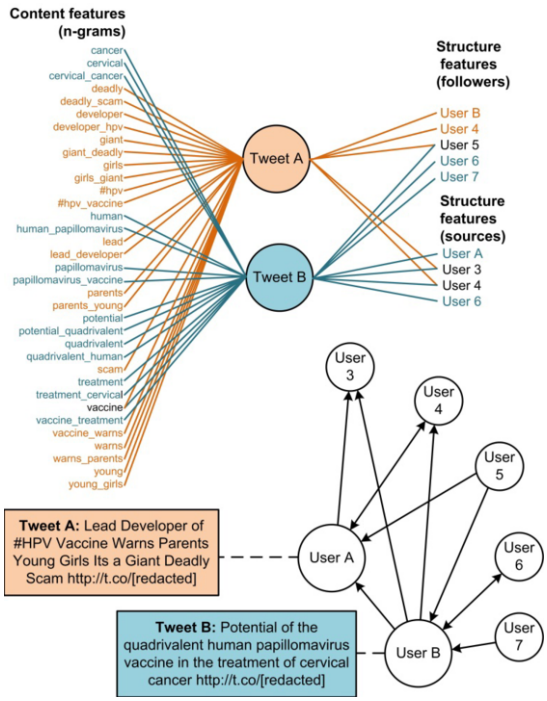

Figure 1– The text is decomposed into n-gram features (left). The follower network for the two users posting the tweets is decomposed into source and follower features (right)

We then determined the source and follower relationships among the set of 21,166 users who tweeted at least once about HPV vaccines. Social connection features were constructed directly from the follower relationships between users. An example of the decomposition is given in Figure 1.

Statistical analysis of content and connection features

Using the sample from the training period, we identified content and connection features that were significantly over-represented in one of the two classes by applying Fisher's exact tests to each feature and then a Bonferroni correction. To examine how low-frequency features might affect the performance of classifiers in the training and testing periods, we also relaxed the inclusion criteria to create alternative sets of features to be used as inputs to the classifier training. The first included all features for which the p-values were less than 0.05, and the second included the set of all features represented in at least three tweets in the sample.

The frequencies of the features exhibiting significant associations in period one were then compared to their frequencies in period two, to measure how the associations may degrade over time. For each of the sets of significant features, we calculated the proportion of features that retained a significant over-representation in the same class.

Classification algorithms

To demonstrate how the temporal variation in the content and connection information might affect the performance of supervised machine learning classifiers, we demonstrated the approach by constructing classifiers using support vector machine (SVM) methods. SVM classifiers have been widely applied in text-based classification [23, 24], and sentiment analysis [25, 26], and are considered the standard and the most appropriate classifier for unbalanced datasets and a large number of features. We chose to apply radial basis function kernels [27], and used consistent parameter values across all the classifiers in order to avoid retrospectively influencing the reporting of the performance.

Feature selection methods are heuristics that are used in the training of machine learning classifier to improve performance by ignoring features that are not useful, and including combinations of features that are best able to discriminate between classes. We applied a hybrid method of forward selection and backward elimination [28, 29].

Classifier construction and testing in the training period was undertaken using a ten-fold cross validation. Note that we determined the potential features using the statistical analysis covering the entire training period. In the testing period (the subsequent three months), the classifiers were applied directly to the full set of tweets from the period as a holdout set, in order to examine the temporal degradation. To compare the classifier performance from training to testing periods, we calculated the standard performance measures: precision, recall, accuracy, and F_1-score. The research project was approved by the Human Ethics Advisory Panels of The University of New South Wales and Macquarie University.

Results

Temporal degradation in content and connection features

From the set of 42,533 unique English-language tweets spanning six months, a random sample of 2150 were extracted and then manually labelled as anti-vaccine or otherwise. After pre-processing, 884 tweets remained in the sample in the first six months (training period), and these came from 877 unique users. Applying Fisher's exact tests and Bonferroni corrections, we identified text fragments and social connections that were found to be significantly more frequent in one class relative to the other (Table 1).

Table 1– The frequency of content and connection features compared across the two periods

Characteristic Set	Number of unique tweets	Number of anti-vaccine tweets (%)	Number of significant features	Features that were no longer significant (%)	Features that switched direction (%)	Features that were still significant (%)
Bigrams (content)						
Bonferroni-corrected	884	247 (28%)	25	24 (96%)	0	1 (4%)
p-value <0.05	884	247 (28%)	232	228 (98%)	2 (0.86%)	2 (0.86%)
Followers (connections)						
Bonferroni-corrected	877	220 (25%)	73	0	0	73 (100%)
p-value <0.05	877	220 (25%)	542	220 (41%)	0	322 (59%)
Sources (connections)						
Bonferroni-corrected	877	220 (25%)	82	2 (2.5%)	0	80 (98%)
p-value <0.05	877	220 (25%)	494	183 (37%)	0	311 (63%)

When the same features were then compared across classes in the tweets from the testing period, the comparison showed that only 1 of 24 (4%) of the content features were also significant in the subsequent three months (Figure 2). In comparison, 80 of 82 (98%) of the connection-based source features were also significant in the subsequent three months, as well as 73 of the 73 (100%) of the connection-based follower features (Table 1). The results show that very few text-based features retained their significant differences in the testing period, while social connections nearly always retained their significant differences in the testing period.

It might be expected that the reason why connection features are stable from one period to the next is because the same users are responsible for anti-vaccine tweets in both periods. However, among the users in the tweets sampled from the training period (877 users), and the testing period (797 users), only 4.1% of the users (66 of 1,608) appear in both samples. Extending this analysis to consider all original tweets in the two periods and not just the sampled sets, only 11.3% of users (2,382 of 21,166) posted tweets about HPV vaccines in both periods. The small overlap suggests that the connection features were stable across the two periods not as a consequence of tweets being posted by the same users, but because users posting about HPV vaccines for the first time in the six month period often followed the same accounts as other users who expressed similar opinions.

Classifier training and testing in period one

The classifiers trained using only connection features produced similar levels of accuracy (often with higher precision and lower recall) to the classifiers that were trained using only content features (Table 2). The best-performing classifier that only used connection features achieved an accuracy of 89.4% (95% CI 87.4-91.4), which was roughly equivalent to the best-performing classifier trained using only content features (89.8% accuracy; 95% CI 87.9-91.8). The overall best-performing classifier in the training period was constructed from both content and connection features (94.4% accuracy; 95% CI 93.1-96.3), and used 23 social connections and 28 text-based features.

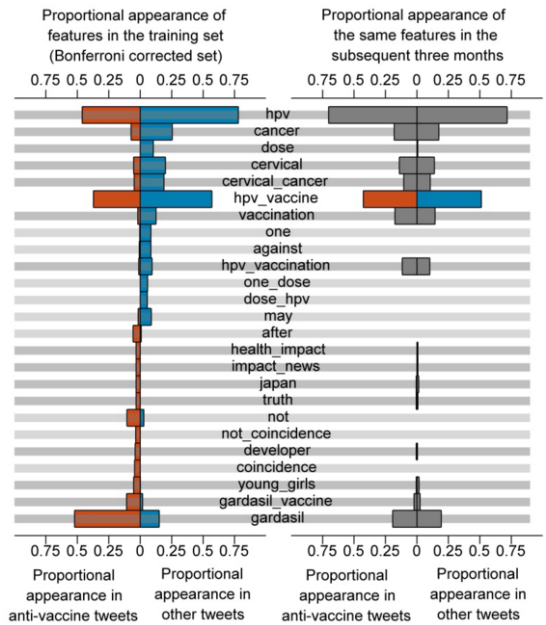

Figure 2– The proportional appearance of text fragments from the Bonferroni-corrected set of content features from the first three months (left), and the subsequent three months (right). Features with non-significant differences in the testing period are illustrated in grey

The performances of the classifiers that were constructed from connection-based source features were slightly better than classifiers from connection-based follower features. The accuracies of classifiers that selected from sources (86.2% to 88.0%) were slightly higher than their direct counterparts that were selected from followers (84.0% to 87.1%). The complete results are given in Table 2.

Table 2– The performances of classifiers trained to classify anti-vaccine tweets within the training period (the first three months)

Input Feature Set	Features selected	Precision	Recall	F1-score	Accuracy (95% CI)
Content: bigrams					
Bonferroni correction	11	0.74	0.56	0.63	82.0 (79.5-84.5)
p-value < 0.05	26	0.77	0.70	0.73	85.8 (83.5-88.1)
threshold = 3	37	0.88	0.74	0.82	89.8 (87.9-91.8)

Classifier testing in period two

The performance of the classifiers was not sustained in the testing period, and the performance degradation observed from the training period to the testing period varied substantially across the classifiers (Table 3). The classifiers that included content features and had the highest accuracies in the training period exhibited the greatest degradation in performance when tested on tweets from the testing period.

Classifiers that used social connection information tended to perform similarly in the training and testing periods, with smaller changes in accuracy compared to the content-based classifiers (Table 3). These results are consistent with the statistical analysis of the features, which showed that the social connections were more consistently distributed across the two classes in the training and testing periods, compared to the text fragments.

Table 3 – The change in performance when applying the classifiers to the testing period (the subsequent three months)

Classifier	Accuracy (95% CI)	Accuracy change (%)
Bigrams (content)		
Bonferroni correction	85.2 (82.9-87.5)	3.2
p-value < 0.05	82.6 (80.1-85.1)	-3.2
threshold = 3	53.6 (50.4-56.9)	-36.2
Followers (connections)		
Bonferroni correction	86.0 (83.6-88.4)	2.0
p-value < 0.05	85.5 (83.1-87.9)	0.0
threshold = 3	84.1 (81.6-86.6)	-3.0
Sources (connections)		
Bonferroni correction	88.6 (86.4-90.8)	1.9
p-value < 0.05	81.6 (78.9-84.3)	-4.6
threshold = 3	87.3 (85.0-89.6)	-0.7
Bigrams, sources (both)		
Bonferroni correction	88.6 (86.4-90.8)	0.8
p-value < 0.05	82.2 (79.5-84.9)	-10.9
threshold = 3	87.1 (84.8-89.4)	-6.7

The two best performing classifiers were capable of distinguishing anti-vaccine tweets from all other tweets with 88.6% accuracy in the testing period. One was trained using only social connections and the other was trained using social connections and text fragments.

Discussion

We demonstrated that social connection information can be used to improve classifiers capable of identifying anti-vaccine opinions for HPV vaccines on Twitter, addressing the temporal degradation associated with using content features alone. While we have examined this phenomenon for only one topic, the results suggest that this approach may help to reduce the frequency at which social media surveillance systems would need to be updated through manual intervention.

Previous attempts at using social network information as features in supervised machine learning for Twitter classification have demonstrated reasonable performance – the best reported accuracies on various datasets were 68% and 73% using information from replies and retweets [30, 31], and between 58% and 77% using follower connections [32-34]. We believe our study is the first to demonstrate the difference in temporal degradation across classifiers constructed from content and social connection features.

The results suggest that information about who users follow, rather than who follows them, may be more useful for predicting the direction of their expressed opinions. A plausible explanation for this comes from the friendship paradox [35]. For any given user posting a tweet about HPV vaccines, the users they follow are likely to have more followers on average. More popular and influential users are expected to be better connected to the communities that tweet about HPV vaccines and as a consequence, may produce more useful features. The results may also suggest that there is a core of users that may be influential in vaccine information communities and that their followers tend to express similar opinions as a consequence of homophily or contagion [12, 14].

Limitations

There were several important limitations to the experiments reported here. Firstly, rate-limited access to Twitter precluded the instantaneous collection of user information each time we captured a relevant tweet, so calls to the API were staggered throughout the period and the information was collected only once for each user. However, given the stability of the social connections and the relatively small proportion of users that tweeted in both periods, this limitation is unlikely to have affected the conclusions. In addition, we did not apply any query expansion methods or evaluate the overall quality of the search terms we used.

Secondly, alternative feature space constructions and selection methods could have been chosen to produce classifiers, and these may have yielded different results. Specifically, there may be combinations of time-invariant text fragments that could out-perform our most accurate classifier (88.6% accuracy).

Finally – and importantly – we prospectively chose to demonstrate the results of the statistical analysis by implementing one type of classifier (SVMs using a radial basis function kernel) and fixed the parameter values to balance precision and recall in an unbalanced sample. If we had chosen other parameter values, different kernels, or other less appropriate machine learning algorithms, the results may have been different. However, since we tested the significant associations for all content and connection features independently of the classifier training and testing, our conclusions are largely independent of, but confirmed by, the construction of the classifiers.

Conclusion

For the task of classifying tweets about HPV vaccines as anti-vaccine or otherwise, information about the social connections between users provided a useful addition to the content of what people write. In particular, we showed that it is possible to use information about the users that people follow online to help predict their opinions. Our findings also suggest some potential avenues for the development of opinion forecasting – prospectively predicting the opinions of individuals and populations based on their social connections, rather than reactively classifying their opinions based on what they write.

Abstract

Traditionally, epidemiologists have counted cases and groups of symptoms. Modeling on these data consists of predicting expansion or contraction in the number of cases over time in epidemic curves or compartment models. Geography is considered a variable when these data are presented in choropleth maps. These approaches have significant drawbacks if the cases counted are not accurately diagnosed. For example, most regional public health authorities count influenza like illnesses (ILI). Cases of these diseases are designated as ILI if the patient exhibits fever, respiratory symptoms, and perhaps gastrointestinal symptoms. Several molecular epidemiological studies have shown that there are many pathogens that cause these symptoms and the relative proportions of these pathogens change over time and space. One way to bridge the gap between syndromic and genetic surveillance of infectious diseases is to compare signals of symptoms to pathogens recorded in molecular databases. We present a web-based workflow application that uses chief complaints found in the public Twitter feed as a syndromic surveillance tool and connects outbreak signals in these data to pathogens historically known to circulate in the same area. For the pathogen(s) of interest, we provide Genbank links to metadata and sequences in a workflow for phylogeographic analysis and visualization. The visualizations provide information on the geographic traffic of the spread of the pathogens and places that are hubs for their transport.

Keywords:

Infectious disease; Epidemiology; Foodborne Diseases; Public health surveillance; Twitter Messaging; Geo-referenced data; Genomics.

Introduction

Influenza-like illness (ILI) refers to a group of conditions such as fever, fatigue, cough, loss of appetite, aches, and sometimes gastrointestinal symptoms. The ILI concept remains a cornerstone of syndromic disease surveillance. However the pathogens that cause ILIs vary in space, time, taxonomy, and frequency and severity of infection. This gap between what syndromic surveillance purports to measure and what is being missed in terms of biology is striking. For example, in a retrospective study of 16,000 samples from patients clinically diagnosed with pandemic H1N1 influenza during April-July 2009 in Scotland, only 9% of the samples were tested positive via real-time PCR for pandemic H1N1 virus [1].

Similar studies of the molecular etiology have been conducted for respiratory tract infection in the Netherlands [2] (Table 1), United Kingdom [3] (Table 1), France [4], and China [5,6]. In the 2014, the United States had one of the first patients presenting the symptoms of fever and vomiting at an ER after a recent travel from West Africa and was sent home with antibiotics instead of being diagnosed for Ebola [7].

Table 1– A comparison of two similar studies illustrating temporal and geographic diversity of pathogens underlying lower respiratory tract diagnoses

NCBI taxid	Pathogen	Graffelman Netherlands	Creer UK
0	No pathogens detected	46.00	31.00
480	*Moraxella catarrhalis*	0.69	0.87
727	*Haemophilus influenzae*	6.92	4.37
810	*Chlamydia spp.*	1.38	0.00
1313	*Streptococcus pneumoniae*	4.85	13.10
2104	*Mycoplasma pneumoniae*	6.23	0.87
10535	Adenovirus	1.38	0.00
11118	Coronaviruses	0.00	4.37
11216	Parainfluenza virus type 3	2.08	0.00
11309	Influenza A and B pooled	0.00	16.59
197911	Influenza A	0.69	0.00
197912	Influenza B	24.92	0.00
12059	Rhinoviruses	1.38	22.71
12059	Enteroviruses	0.00	1.75
12730	Parainfluenza	0.00	2.62
12814	Respiratory syncytial virus	2.77	1.75
77133	Other bacteria	0.69	0.00
	Sum	100.00	100.00

Table 1 shows the percent of total pathogens underlying lower respiratory tract diagnoses identified by PCR and microbiological techniques by Graffelman and colleagues in the Netherlands (November 1998–June 2001) [2], and those identified by Creer and colleagues using real time PCR in the United Kingdom (May 2000-April 2001) [3]. Note that there are some differences in granularity of influenza testing and enterovirus testing.

We have created a system to: 1) bridge the gap between syndromic and genetic surveillance of infectious diseases and 2) provide information on the historical presence of pathogens associated with a cluster of related symptoms as identified in natural language from a public stream of a microblogging system, Twitter™.

Methods

We have created a live web-based workflow application (Figure 1) where analysts can obtain up-to-date syndromic data from a social media source. We correlate Tweet content to pathogens known to circulate in that geographic area using information such genetic data and metadata for pathogens of interest that has been published by subject matter experts.

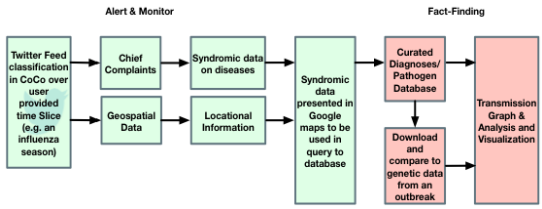

Figure 1. The data and analysis workflow consists of an alert and monitor phase focused on event modeling of a Twitter feed for clusters of Tweets with similar natural language corresponding to chief complaints.

Figure 1 shows that the rest of the workflow enables an analyst to perform fact finding by querying databases for sequence and metadata of pathogens that historically circulate in the locality of the Tweet cluster of interest. The analyst can download data from the links to Genbank (http://www.ncbi.nlm.nih.gov) to be combined with the fresh sequence and metadata from an out-break and/or can proceed with the transmission graph analysis and geographic visualization. The software modules implemented for the alert and monitor phase of the workflow is displayed in Figure 2.

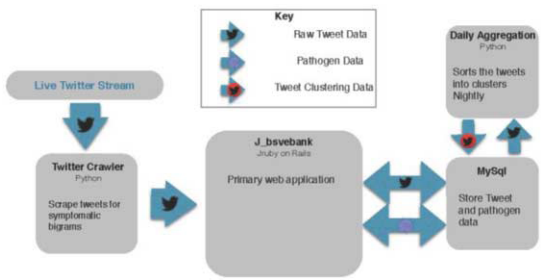

Figure 2- Software modules implemented for the alert and monitor part of the workflow. Arrows signify the flow of data from each module to the others in the system.

Tweets are gathered from the public stream, (https://dev.twitter.com/streaming/public) which serves a 1% sample of Tweets daily. Tweets are geocoded using user reported locations or after sending user profile data through Nominatim (http://nominatim.openstreetmap.org/) for matching geographical metadata to textual place names.

This work is done in python environment separate from the primary JRuby on Rails application to balance the load processing load. As Tweets are geocoded, they are sent to the Rails server. The Rails server receives the Tweets and stores them in a MySQL database where, once a night, they are indexed into Tweet clusters to be seen by the analyst the next morning or as a response to a retrospective query.

The natural language in Tweets is classified using the Bayesian chief complaint classifier (CoCo) of the Real-time Out-break and Disease Surveillance project (RODS) [8] to deter-mine potential relevance of Tweets by comparing their content to a list of 388 bigrams associated with infectious diseases (https://www.scribd.com/doc/250640730/terms-for-syndromic-surveillance).

Natural language terms from the Tweets of interest are then assigned to one of the seven classifications: hemorrhagic, neurological, rash, botulinic, respiratory, constitutional, gastrointestinal, or other, as determined by CoCo. These classifications allow us to identify and group Tweets in the light of their potential value as syndromic indicators. This information is stored in a MySQL database and can be searched by querying specific areas around the globe and slices of time.

In the next processing stage, CoCo and the geocoded Tweet clusters are associated with the pathogen datasets curated from NCBI's population genetic sequence database (aka "popset" http://www.ncbi.nlm.nih.gov/popset). These datasets contain orthologous genetic sequences, geographical information, temporal data, and host metadata from the strains of pathogens.

The data found in these related popsets are then subjected to multiple sequence alignment with MAFFT under the default settings [9]. The alignment is then subjected to phylogenetic tree search with TNT under the default settings [10]. At the visualization stage, a randomly chosen single phylogeny of the optimal set found is used to generate a transmission graph. The transmission graph is created by using the ancestor-descendent changes in the "place of isolation" character as optimized on the phylogeny. The transmission graph is assessed for betweenness and centrality, and displayed in Google Maps™ (GM) using in house code for phylogenetic visualization and mapping as described by Janies et al. [13].

Results

The application at work

At first view, an analyst is greeted with an interface dominated by a GM instance. An analyst can use search and filter tools located in separate sliding windows to select syndromic data that may be of interest or view all of the most recently recorded data. After selecting syndromic data the view focuses on the map where the relevant Tweet data is displayed and our "alert and monitor" process begins.

Our alert system is based on the concept of Tweet clusters. Tweet clusters share geography, collection date range, and natural language associated with the symptoms of infectious diseases. The number of Tweets in a cluster is recorded on a daily basis. This allows us to use historic Tweet cluster data in building a distribution for statistical analysis of incoming Tweets. When analyzing a new Tweet cluster, a collection of data is generated from the past clusters that were gathered over a period of three months.

For each bigram discovered within a Tweet we calculate the average number of times that bigram has appeared in the past three months, a standard deviation factor for the bi-gram's expected appearance, and a value representing how many times the bigram's appearance exceeds the standard deviation.

We use circles to visualize and represent Tweet clus-ters. The color of a circle indicates the intensity of the syndromic activity based on the statistical analysis and the circle size is proportional to the number of Tweets in the cluster. The circles are placed onto the GM at the respective geographic centers of the Tweet clusters (Figure 3).

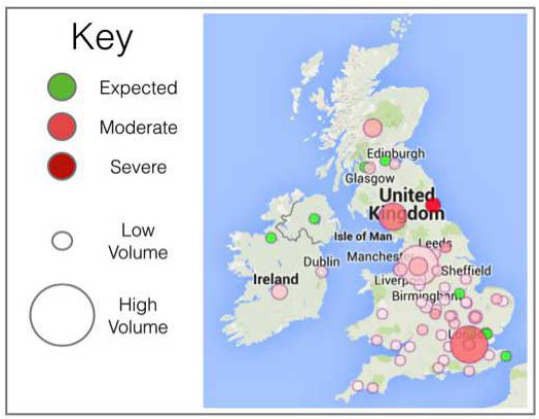

Figure 3- Tweet clusters from a winter day in 2015 the UK and Ireland.

Further analysis can be performed on a Tweet cluster by clicking on its circular icon on the GM. A window will drop down to display a series of statistics related to the chosen Tweet cluster in two separate tables. The first table displays the statistics describing cluster coloration within the alert system, while the other organizes the bigrams found in Tweets of the cluster into their respective CoCo classifications.

The first table informs the analyst whether it is worthwhile to to further investigate a Tweet cluster. This table displays the bigram of interest, its CoCo classification, the average number of times this bigram has appeared in the past 90 days, the standard deviation from the average, and the current appearance count. These values determine the color of the cluster in the alert system, and may influence users' interest to further explore the cluster.

Tweets are clustered by various CoCo classifications. The second table presents options to display more information about the classifications within a cluster. The count of Tweets associated with the CoCo classification is shown. To dig deeper, an analyst may view the actual Tweets or a pie chart summarizing the distribution of chief complaints (Figure 4).

For a cluster of interest, an analyst can query the population set database using CoCo diagnosis and locality information. Querying the pathogen population dataset returns a taxonomy pie chart of the pathogens in the area (Figure 5) and a series of scrollable datasets of genetic, geographic, and temporal metadata.

Each accession number within these datasets is linked to the National Center for Biotechnology Information's Genbank (http://www.ncbi.nlm.nih.gov). Using these links the analyst can leverage the information and tools in Genbank such as cross references to nucleotides, proteins, publications on the clinical or zoonotic aspects of the pathogen, basic local alignment to similar sequences, structural information, etcetera) (Figure 6).

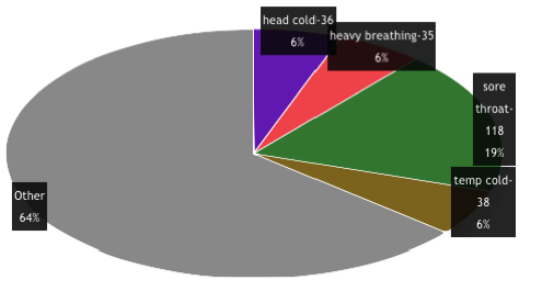

Figure 4- A view of Tweets associated with respiratory complaints in the United Kingdom in late 2014-early 2015.

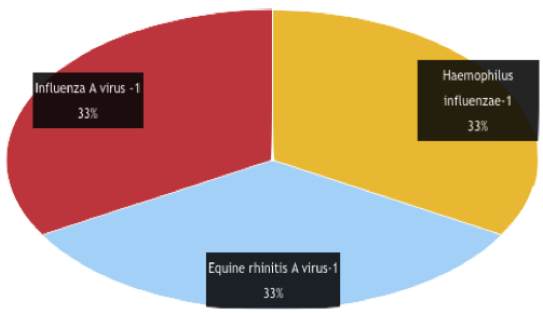

Figure 5- Pathogens associated with Tweets with respiratory complaints in the United Kingdom.

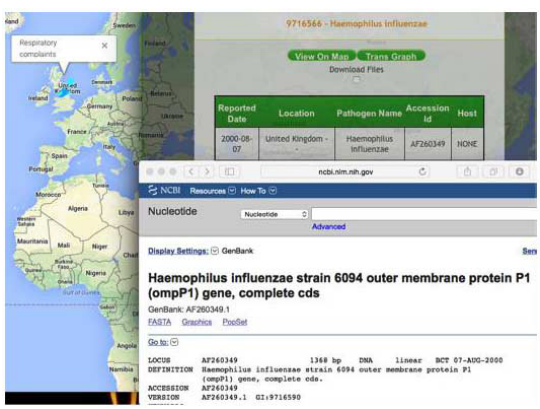

Figure 6. The analyst selected to view a Haemophilus influenzae genetic dataset associated with the classified Tweet in the United Kingdom.

For a pathogen population set of interest, the analyst can select to view its geographical diversity on GM and follow through with a phylogeographic visualization workflow. Our workflow does all the data wrangling including multiple sequence alignment, phylogenetic tree search, metadata optimization and visualization on the tree. The analyst can choose to view the results as an abstract and static transmission graph (Figure 7) or a literal and animated transmission map on GM (Figure 8). In Figure 7, A node represents geographic location for each isolate. The transmission graph reflects historical transmission links as viewed by the character evolution on a phylogeny. The size and darkness of the circles represent relative importance of a geographic place in spreading a pathogen in terms of a betweenness metric (e.g., the UK is important in this case)

[13]. The thickness of the lines and the size of ar-rows represent frequency of historical transmissions. In Figure 8, A transmission event is represented by a weighted link between two locations where the thickness of the link indicates the transmission frequency. The direction of the transmission is denoted by an animated arrow moving from transmission source to destination with a speed based on the transmission frequency (http://secure-basin-8938.herokuapp.com/medinfo.gif).

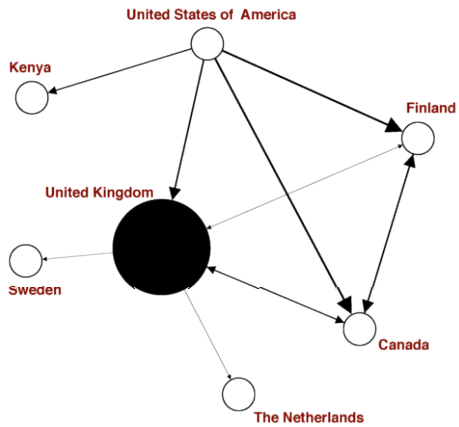

Figure 7. A transmission graph of Haemophilus influenzae isolates.

Figure 8. A screen shot from an animated transmission map of Haemophilus influenzae.

Discussion

We have created a bridge between syndromic and genetic surveillance of infectious diseases. Our system collects and classifies Tweets every day. Thus the results are dynamic. Between June and December of 2014 we classified over 1,000,000 Tweets and associated the Tweet clusters with corresponding pathogens selected from over 14,000 pathogen sequence datasets and metadata in the system. Siunce a human in the loop is important, the system is currently being prepared for usability testing with biosurveillance analysts.

The use case illustrated in the figures is derived from a study of molecular variations in light of vaccine design for non-typeable Hemophilus influenza [11]. The bacterium is a member of the Pasteurellaceae family and was once thought to be the cause of influenza. Hemophilus influenzae causes respiratory and other infections in humans. The worldwide spread of this pathogen is understudied, but the recent reports have shown that closely related strains are geographically diverse [12], which is consistent with our analysis.

The betweenness analysis can be carried out in conjunction with the social media analysis or on its own. The phylogenetic visualization modules of the system have also been used in the studies of H7 influenza [13] and Salmonella [14].

Conclusion

Syndromic surveillance is popular, as the data is growing rapidly and often widely shared. Given the current state of affairs, areas for improvement include the collection of more syndromic and genetic data. More data will provide denser information sets with which to connect syndromes and pathogens. Syndromic data can be expanded with the collection from sources other than Twitter and the including there in of multiple human languages. Next generation sequencing application in the public health settings is being widely adopted. Genetic data is often not rapidly shared but this practice is changing in some fields [15].

A major breakthrough will come when public health can rely primarily on genetic surveillance. Genetic surveillance can be used to accurately diagnose the pathogen underlying an outbreak. Accurate diagnosis is vital for treating patients well. Additionally, public health depends on appropriate use of antivirals and antibiotics to abate the evolution of the drug resistant organisms. As small portable low cost sequencing devices become available, we envision a future where genetic surveillance will be widespread and rapid. If these data are shared in a concerted fashion and there is support for development of tools to make sense of the data, then public health surveillance systems based on the biology of diseases will be within reach [16, 17]. If bio-surveillance analysts can devise tools to keep pace with the volume of these data and find new ways to work with it, we will be better able to anticipate the spread and flow of infectious diseases.

Abstract

***Objectives**: To explore automatic methods for the classification of biomedical vocabularies based on their content. **Methods**: We create semantic group profiles for each source vocabulary in the UMLS and compare the vectors using a Euclidian distance. We explore several techniques for visualizing individual semantic group profiles and the entire distance matrix, including donut pie charts, heatmaps, dendrograms and networks. **Results**: We provide donut pie charts for individual source vocavularies, as well as a heatmap, dendrogram and network for a subset of 78 vocabularies from the UMLS. **Conclusions**: Our approach to fingerprinting biomedical terminologies is completely automated and can easily be applied to all source vocabularies in the UMLS, including upcoming versions of the UMLS. It supports the exploration, selection and comparison of the biomedical terminologies integrated into the UMLS. The visualizations are available at (http://mor.-nlm.nih.gov/pubs/supp/2015-medinfo-br/index.html).*

Keywords:

UMLS; Semantic Groups; Terminology Fingerprinting; Content-based Classification.

Introduction

The Unified Medical Language System® (UMLS) is a terminology integration system [1]. It provides broad coverage of the biomedical domain, from disorders to procedures to drugs to anatomical structures. While some source vocabularies focus on a subdomain of biomedicine (e.g., RxNorm for drugs), others, such as SNOMED CT and the NCI Thesaurus, provide coverage across biomedicine. However, selecting a biomedical terminology remains challenging for users, because there is no description of content coverage, i.e., no description of which subdomains are covered by a given terminology.

The UMLS used to provide a classification of source vocabularies based on usage. This classification, performed manually, leveraged the Medical Subject Headings (MeSH). This classification was heterogeneous, as it mixed usage and content categories. For example, categories such as "Nursing" and "Complementary Therapies" reflect usage, whereas the categories "Disease" and "Procedures" are based on content. Moreover, classification by usage does not necessarily align with classification by content. For example, the International Classification for Nursing Practice (ICNP®) and Nursing Interventions Classification (NIC) are both "Nursing" terminologies, although NIC predominantly contains therapeutic procedures, while ICNP also contains content about diagnoses and outcomes. In addition, source vocabularies may need to be classified into more than one category. Another limitation of this classification is that only the most frequently updated sources in the Metathesaurus were considered, because manual classification is labor-intensive. Overall, while useful to new users, this classification was imperfect and difficult to maintain for new versions of the UMLS in which new terminologies may have been introduced or modified significantly.

The objective of this work is to explore automatic methods for the classification of biomedical vocabularies based on their content. More specifically, we create a "fingerprint" (i.e., semantic profile) for each terminology in the UMLS by leveraging the categorization of UMLS concepts into semantic groups. These semantic group profiles form the basis for classifying and comparing the biomedical vocabularies based on their content. This classification could help terminology users to better understand the clinical or research purposes for which the terminologies are needed. Our approach is fully automatic, does not require any additional knowledge about the vocabularies, and can be easily deployed. We also explore several visualization techniques to render this classification. The semantic fingerprints we provide for biomedical terminologies could complement, if not replace, the classification of UMLS source vocabularies provided earlier.

Background

The Unified Medical Language System. The Unified Medical Language System® (UMLS) is assembled by integrating 179 source vocabularies. The UMLS Metathesaurus (version 2014AB) currently contains about 3.1 million concepts, i.e., clusters of synonymous terms coming from various source vocabularies. Each Metathesaurus concept is assigned at least one semantic type from the UMLS Semantic Network, a small network of 133 semantic types organized into a tree structure. The semantic types are partitioned into fifteen semantic groups (McCray et al. 2001), which represent broad subdomains of biomedicine, such as *Anatomy*, *Chemicals & Drugs*, and *Disorders*. Every semantic type is categorized into only one semantic group. The fifteen semantic groups are listed in Table 1, along with the number of Metathesaurus concepts in each group. In practice, the semantic groups provide a coarse categorization of the Metathesaurus concepts based on the principles of semantic validity, parsimony, completeness, exclusivity, naturalness, and utility. The semantic groups have been used in several applications, including visualizations of highly conceptual spaces [2], discovery of inconsistencies in the categorization of UMLS concepts [3], word-sense disambiguation [4], and quality assurance of value sets [5].

Visualization and cognition. We present different graphical representations of vocabularies based on their semantic content. There exists a broad body of literature describing the impact of visual displays on not only the speed of decision-making, but also its accuracy [6-9]. Cognitive theories provide context on the processes involved in visualizing information. This can range from the theories of Cleveland and McGill, who propose a set of elementary visual tasks for interpreting displays, to Pinker's models of cognitive processing from raw visual information to encoded visual descriptions [10, 11]. We also leverage some of the visualization techniques used for genomic datasets [12]. In the context of fingerprinting biomedical terminologies, visualization is an important component of presenting the information in a succinct manner to facilitate use by a broad range of stakeholders within the biomedical community.

Table 1– Distribution of Metathesaurus concepts by semantic groups

Semantic group name	Abbreviation	# concepts
Activities & Behaviors	ACTI	4,385
Anatomy	ANAT	122,298
Chemicals & Drugs	CHEM	813,426
Concepts & Ideas	CONC	48,711
Devices	DEVI	45,883
Disorders	DISO	544,829

Physiology	PHYS	140,146
Procedures	PROC	374,195

Methods

Our method for classifying biomedical vocabularies based on their content can be summarized as follows. For each source vocabulary in the UMLS, we first create vectors reflecting the distribution of concepts among semantic groups (i.e., semantic group profiles). We then compare the semantic group profiles using a Euclidian distance. Finally, we apply several visualization techniques to the semantic group profiles.

Creating semantic group profiles

For each UMLS source vocabulary, we compute the frequency distribution of its concepts among the 15 semantic groups, which we record in a 15-dimensional vector. This is what we call the semantic group profile (or semantic fingerprint) of a source vocabulary. For example, SNOMED CT spans a variety of semantic groups, including *Disorders* (31%), *Chemicals & Drugs* (23%), *Procedures* (11%), *Anatomy* (7%) and *Devices* (3%). In contrast, 99% of the concepts from the Foundational Model of Anatomy (FMA) belong to the semantic group *Anatomy*. Its semantic profile is sparse, with few semantic groups other than *Anatomy* having a value other than 0. The set of vectors computed for each terminology forms a matrix of terminologies by semantic groups.

Comparing semantic group profiles

In order to compare two semantic group profiles, we use a Euclidian distance metric, that is, the straight line distance between two vectors, i.e., between two semantic group profiles. (We also tested other similarity metrics including cosine, Jaccard, and Dice. However, the Euclidian distance provided a range of values more suitable for defining groups of source vocabularies using hierarchical clustering.) We generate a distance matrix by calculating the Euclidian distance between terminologies pairwise.

We then use an agglomerative method of hierarchical clustering to group together similar semantic group profiles. The agglomerative hierarchical clustering algorithm starts with a distance matrix and identifies the pair of source vocabularies that are the most similar. This forms the first cluster. The distance matrix is then recalculated, with complete linkage defining the distance between clusters as the largest distance between any two of its elements. The elements of the matrix are compared to find the next closest pair between sources or clusters. This is repeated until a single agglomerative cluster of all source vocabularies is formed.

Visualizing semantic group profiles

We propose three different visualizations for the semantic group profiles depending on what we want to emphasize. Namely, we visualize single semantic fingerprints (i.e., single terminologies) with "donut" pie charts, sets of semantic fingerprints (i.e., multiple terminologies) with heatmaps, and associations between terminologies and semantic groups with network representations.

Visualizing single semantic group profiles – "donut" pie charts

We use ***"donut" pie charts*** for visualizing single semantic group profiles. In this visualization, the source is represented as a ring. The source ring contains arcs corresponding to each semantic group. The size of the arc is proportional to the proportion of the corresponding semantic groups in the source. In addition to displaying the profile of a give terminology, this representation also makes it easy to compare different profiles.

Visualizing sets of semantic group profiles – heatmaps and dendrograms

We provide a ***heatmap*** representation of the data found in the distance matrix. The source vocabularies are listed on the x-axis and the semantic groups are listed on the y-axis. Density on the heatmap corresponds to the percentage of all concepts within a source vocabulary that is found in a given semantic group. Density is color coded, with red for high percentages of a semantic group in terminology and yellow for low percentages. As a result, scanning a vertical slice (column) of the heatmap provides a visual representation of the semantic group profile for a source vocabulary. Conversely, by scanning a horizontal slice (row) of the heatmap, a user can easily identify those source vocabularies with a large proportion of concepts for this semantic group.

Additionally, we generate a ***dendrogram*** to visualize the hierarchical clustering of the source vocabularies. Short branches on the tree represent terminologies with similar semantic group profiles, while long branches represent more dissimilar source vocabularies. The dendrogram can be cut to obtain a given number of clusters. Clustering also helps contrast groups of terminologies with similar semantic group profiles within groups and different profiles across groups. An arbitrary number of clusters can be produced, depending on the threshold of similarity among clusters used.

Visualizing associations among terminologies – networks

In order to visualize associations among terminologies through semantic groups, we apply a bipartite network visualization to the semantic group profiles for visual display of content across multiple source vocabularies.

- Nodes represent semantic groups on the one hand and source vocabularies on the other.

- An edge from source S to semantic group G is drawn if the source vocabulary contains at least some percentage of concepts in G.

The network representation makes it easy to identify which source vocabularies share a high concentration of a particular semantic group, as these vocabularies all have edges to this semantic group. Different networks can be obtained by selecting different thresholds for the minimum proportion of concepts from semantic groups.

Implementation

All statistical analyses and heatmap visualization were performed using the R statistical software. Network display and "donut" pie chart leverage the JavaScript library "D3 for Data-Driven Documents".

Results

Visualizing single semantic group profiles – "donut" pie charts

Figure 1 shows the semantic group profiles of four UMLS source vocabularies. As mentioned earlier, the Foundational Model of Anatomy (FMA) contains almost exclusively anatomical concepts, displayed in light green. Similarly, the Online Mendelian Inheritance in Man (OMIM) vocabulary essentially contains gene (green) and disease (red) concepts. In contrast, SNOMED CT, a general clinical terminology, contains concepts from almost all semantic groups, with a large proportion of disease concepts. Finally, while the National Drug File-Reference Terminology (NDFRT) is a drug terminology, it also contains not only a majority of drug concepts (dark green), but also large numbers of concepts from other semantic groups, including *Disorders* (red) and *Physiology* (orange), because NDF-RT drugs are described drugs in terms of physiologic effect and mechanism of action (*Physiology*), as well as therapeutic intent (*Disorders*).

Visualizing sets of semantic group profiles – heatmaps and dendrograms

Figure 2 shows the heatmap and dendrogram resulting from the hierarchical clustering of 78 source vocabularies. (Although the distance matrix was computed for all source terminologies, the display is limited to these 78 vocabularies for readability. In practice, we filtered out non-English vocabularies. While translations of vocabularies contain new labels for concepts, their semantic content is identical to that of their English source. We also filtered vocabularies with fewer than 1,000 concepts since their small size limits their overall significance.)

Columns from the heatmap represent the semantic group profiles of individual source vocabularies. For example, the Foundational Model of Anatomy is represented by a single red spot for the semantic group *Anatomy*, while SNOMED CT spans multiple semantic groups in the column. Conversely, the rows of the heatmap reflect the density in concepts from a given semantic group. The large red bar in the lower right corner corresponds to a high density of concepts from the *Disorders* semantic group in disease terminologies.

The clustering algorithm was (arbitrarily) required to produce 6 clusters. Each cluster is rooted by the top subdivisions of the dendrogram (and highlighted by boxes with solid lines on the figure). Clusters range in size from 1 source vocabulary (HGNC) for the leftmost cluster, to 26 source vocabularies for the rightmost cluster. Some clusters are homogenous. For example, cluster 1 contains one gene terminology, cluster 2 contains six procedure terminologies and cluster 4 contains two terminologies primarily containing organisms. In contrast, the remaining clusters are heterogeneous and subgroups can easily be identified within them. For example, the large cluster 3 groups drug terminologies such as RxNorm, device terminologies, such as the Current Procedural Terminology (CPT), and general terminologies, such as SNOMED CT. Similarly, cluster 5 groups organism terminologies, such as the NCBI Taxonomy, anatomical terminologies, such as the Foundational Model of Anatomy (FMA), administrative terminologies, such as the HL7 value sets (HL7V2.5), and terminologies with focus on physiological concepts, such as LOINC and the International Classification of Functioning (ICF). Finally, cluster 6 clearly groups disease terminologies, some of which contain only disease concepts (e.g., ICD 10-CM) and other contain concepts from another group (e.g., genes and diseases in OMIM).

Visualizing associations among terminologies – networks

The bipartite network we created for visualizing associations among terminologies contains two types of nodes. The source vocabularies are represented in green, while the semantic groups are in yellow. Edges are drawn between a source vocabulary and a semantic group if the vocabulary contains at least 5% of concepts from this semantic group. (This arbitrary threshold can be modified to reflect stronger associations.) In Figure 3, source vocabularies that contain at east 5% of concepts from the Disorders semantic group are highlighted. Similarly, as shown in the inset from Figure 3, it is also possible to highlight all semantic groups for a given source vocabulary (i.e., all the semantic groups, whose concepts constitute at least 5% of the source vocabulary).

Discussion

Use cases and applications

The semantic group profiles provide a method for assessing the similarity among source vocabularies in the UMLS. This general technique can be applied to terminology exploration, terminology selection and terminology comparison.

Exploring terminologies

Novice users of the UMLS sometimes have difficulties grasping the differences among the many source vocabularies in the Metathesaurus. While the UMLS Terminology Services browser allows users to find the details about individual Metathesaurus concepts and their relations, it does not provide an overview of sets of concepts in source vocabularies. Our donut pie charts, heatmap and network visualizations provide an overview of the content of the source vocabularies. More specifically, they provide a coarse description of the semantics of these terminologies, making it possible to quickly identify the major semantic areas in a given vocabulary.

Selecting terminologies

One common use case is to select the best terminology for a given application. For example, if an application requires disease concepts, our visualizations make it easier for a user to identify candidate terminologies, i.e., terminologies containing a large proportion of concepts from the semantic group *Disorders*. In practice, a user will look for a large red arc on the donut pie charts, or might scan the *DISO* row on the heatmap, looking for red spots. Alternatively, our user could also select the *DISO* node on the network visualization and explore all source vocabularies linked to it, having set an appropriate threshold for the minimal proportion of concepts from this semantic group required for edges to be drawn.

Comparing terminologies

The heatmap is also the visualization of choice for analyzing sets of source vocabularies, especially after the hierarchical

clustering has grouped together those terminologies that have similar semantic group profiles. The clusters displayed in Figure 2 and presented in the Results section are relatively easy to interpret, with minimal prior knowledge of the terminologies themselves. Similarity clusters can also be quantified, since the basis for clustering is the Euclidian distance computed among the semantic group profiles for individual source vocabularies.

Content-based vs. usage-based classification

Our work was motivated in part by the limitations of the usage-based classification the UMLS documentation used to provide. We compared the two classification approaches for the 55 source vocabularies for which it was available. The general trend is that there is limited overlap between the two classifications. Categories from the usage-based classification are generally associated with several semantic groups, and a given semantic group is generally associated with multiple categories from the usage-based classification, with no obvious patterns in these associations. One exception is the usage-based category "Adverse drug reaction reporting" that contained only one source vocabulary (MedDRA) and majoritarily contains concepts from the semantic group disorders. In fact, the two classifications provide different views on the source vocabularies and are complemantary. For example, it would be impossible to identify consumer health vocabularies or nursing vocabularies simply from the semantic group profiles. However, as mentioned earlier, unlike the manual usage-based classification, our semantic group profiles can be applied automatically to any new version of the UMLS. Finally, another advantage of our method is that, because it is a vector-based representation of the source vocabularies, it lends itself nicely to visual representation.

Limitations

Many concepts have more than one semantic type; however, these multiple semantic types are generally categorized into the same semantic group. Therefore most concepts are categorized by only one semantic group. In fact, only about 1,000 concepts have multiple semantic groups. As a result, the fifteen semantic groups form partition for over 99.9% of all UMLS concepts, and are thus virtually disjoint.

For the purpose of computing the distribution of the concepts from a source vocabulary into semantic groups, the concepts that have multiple semantic groups should logically not be counted more than once. In practice, these concepts are so few in the UMLS that the effect of double-counting them has no significant effect on the frequency distributions.

The assignment of a semantic type to a UMLS concept is sometimes subjective and can be arguable. Many concepts are categorized with multiple semantic types. In contrast, all UMLS concepts are categorized in 15 disjoint semantic groups. Because the semantic groups are broader, the assignment of concept to a group is less likely to be arguable. However, some groups can be viewed as too general for this application. For example, the semantic group "Chemicals" contains both drugs and other chemicals. A user could be interested in retrieving drug vocabularies, rather all chemical vocabularies. As suggested in [13], the grouping of semantic types into semantic groups could be modified to fit the requirements of a particular application.

Future work

In this study we have used our fingerprinting methodology on UMLS terminologies. Leveraging concept mappings among terminologies, our approach could be used to automatically classifiy the content of terminologies in other repositories such as the NCBO Bioportal. The semantic group-based fingerprint could also be used in a broader context, for example to help characterize the content of biomedical articles or clinical texts.

Conclusion

The growth of the UMLS makes it difficult for users to select appropriate source vocabularies for a given purpose. In this article, we present a new method to classify biomedical source vocabularies based on their content. We leverage the high level semantic categorization of concepts in semantic groups to create a profile for each source vocabulary. Our approach is completely automated and can easily be applied to all source vocabularies in the UMLS, including upcoming versions of the UMLS.

To assist the user in the exploration of available source vocabularies, we propose several visualizations reflecting the individual content of source vocabularies (donut pie charts, heatmaps), as well as the relations among source vocabularies (dendrogram, network). We are currently collaborating with the UMLS team to add the graphical representations to the UMLS documentation, as a complement to the classification they already provide.

Abstract

In this paper, the authors report on a study aimed at harmonising two nursing terminologies, the Clinical Care Classification (CCC) and the International Classification for Nursing Practice (ICNP®). As the electronic health record evolves and the need for interoperability extends beyond local and national borders, a degree of standardisation across healthcare terminologies become essential. Harmonising across terminologies results in a) increased consensus relating to domain content and b) improvements in the terminologies involved. Findings from this study suggest that there is much overlap of content in nursing terminologies. The continued harmonisation between nursing terminologies and other healthcare terminologies are recommended to achieve international interoperability.

Keywords:

International Classification for Nursing Practice; Nursing; Health Terminology Standards; Interoperability.

Introduction

The International Council of Nurses (ICN) has supported the ongoing development and maintenance of the International Classification for Nursing Practice (ICNP) for more than 25 years. An early aim of the ICNP Programme was to harmonize nursing and healthcare terminologies to facilitate interoperability in the electronic health records (EHR). The purpose of this study was to initiate harmonisation of the Clinical Care Classification (CCC) System and ICNP with a focus on nursing problems or diagnoses. The source terminology comprised nursing problems in CCC (n=176). The target terminology comprised ICNP problems or negatively judged nursing diagnoses (n=491).

Background

ICN has supported the ICNP since 1989. ICNP is a standardized terminology, available in 17 spoken languages, comprising statements that represent nursing diagnoses, outcomes, and interventions. It is recognized within the WHO Family of International Classifications as a Related Classification and work is underway to harmonize ICNP with SNOMED CT through a Collaboration Agreement with International Health Terminology Standards Development Organisation (IHTSDO) [1]. At the heart of ICNP is an ontology, represented in the Web Ontology Language (OWL) [1]. This facilitates cross-mapping while allowing delivery in a range of formats to suit the needs of its users.

A second Collaboration Agreement [3] guides harmonisation work with the Clinical Care Classification (CCC), a terminology also focused on nursing and designed specifically for computer-based documentation and processing [4]. In common with ICNP, CCC is compositional in nature (particularly with respect to nursing interventions) and covers nursing diagnoses, outcomes and interventions. These similarities may facilitate comparison; they may also add complexity in harmonising the two terminologies.

In addition to its role as a formal reference terminology, ICNP also is often used as an interface terminology, in common with CCC. The diagram below (Figure 1) displays some similarities and differences in the ways CCC and ICNP concepts are organised and highlights the areas of attention in this study: nursing problems (negative diagnoses). In CCC all nursing diagnoses are judged negatively (as problems). In ICNP, nursing diagnoses may be judged as either negative (e.g. pain) or positive (no pain). ICNP positive nursing diagnoses can be used to identify assets, goals or outcomes. Because CCC nursing diagnoses are patient problems, the focus in this study was on ICNP negative nursing diagnoses.

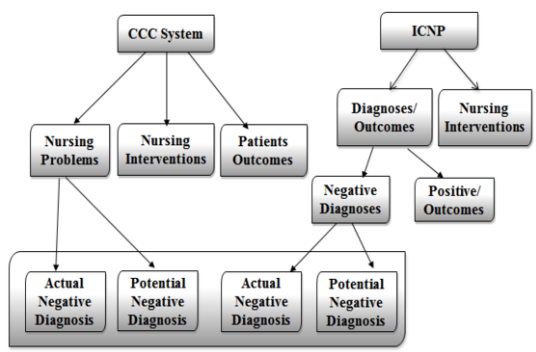

Figure 1 - Structural comparison of CCC and ICNP

Methods

In the mapping process, CCC nursing problems (Version 2.5) [4] acted as the source terms and ICNP nursing diagnoses (2013 release) [5] were the targets. A total of 176 CCC

nursing problems were examined for equivalent concepts in ICNP using a combination of automated and manual (human) processes. The Unified Medical Language System (UMLS) which is a terminology resource maintained by the United States (US) National Library of Medicine (NLM) was used to develop candidate equivalencies, using similar techniques to those described in [6]. Two experts in ICNP and CCC reviewed the candidates independently and compared results. The research team members revised the two sets of equivalencies guided by the CCC textual definitions and ICNP formal definitions. Revisions were made until 100% agreement was achieved among the experts.

Results

For each CCC problem concept an equivalent ICNP concept was identified. Complete coverage of CCC problems in ICNP indicates overlap between the two terminologies. However, not all mappings were one-to-one. Each CCC problem concepts (n=176) mapped to one of 169 equivalent ICNP concepts, which suggests a degree of redundancy in CCC. Specific findings in the equivalency mapping are reported here: (a) one-to-one mappings, (b) one-to-many mappings, (c) actual and potential (risk) problems, (d) use of positive ICNP diagnosis i.e. diagnoses that would be considered 'normal', (e) use of lexical and semantic mappings, and (f) similarities and differences between the two terminologies.

One-to-One Mappings

All but six CCC nursing problems (n=163) had a one-to-one mapping with an ICNP concept. Examples are provided in Table 1.

Table 1 - One-to-One mapping between CCC and ICNP®

CCC Diagnosis	CCC Code	ICNP Diagnosis	ICNP Code
Fall Risk	N33.6	Risk for Fall	10015122
Verbal Impairment	M28.1	Impaired Verbal Communication	10025104
Family Process Alteration	M29.0	Impaired Family Process	10023078
Tobacco Use	N58.1	Tobacco Use	10022247

Many-to-One Mappings

In six cases, more than one CCC concept mapped onto the same ICNP nursing diagnosis. For example, both CCC "Skin Integrity Alteration" (R46.0) and CCC "Skin Integrity Impairment (R46.2) mapped onto the ICNP concept "Impaired Skin Integrity" (10001290) (see Table 2). In these cases, the reviewers considered more than one CCC concept to be semantically equivalent to an ICNP concept, which suggests redundancy among CCC concepts or perhaps a need to revise CCC textual definitions for these six concepts.

Actual problems and potential (risk for) problems

Both CCC and ICNP included judgments about nursing diagnoses regarding potentiality of a problem. All concepts across both terminologies were judged as being either actual or potential (at risk).

Of the 176 CCC nursing diagnoses, 28 (5.7%) might be considered to be a potential problem (or risk) (see Figure 2). Examples of CCC risk diagnoses included: "Risk for Fall" and "Suicide Risk". ICNP includes these concepts among its much larger number of 113 potential problems (risks), for example "Risk for Complications during Pregnancy".

Table 2 - Many-to-One mappings between CCC and ICNP

CCC Nursing Diagnoses (13 of 176)	ICNP Nursing Diagnoses (6 of 169)
A01.0 – Activity Alteration A01.1 – Activity Intolerance	10000431 – Activity Intolerance
A01.5 – Physical Mobility Impairment Q44.3 – Kinesthetic Alteration	10001219 – Impaired Mobility
E11.0 – Family Coping Impairment E11.2 – Disabled Family Coping	10034789 – Impaired Family Coping
M32.0 – Socialization Alteration M32.1 – Social Interaction Alteration	10001022 – Impaired Socialization
038.0 – Self-Care Deficit 038.1 – Activities of Daily Living Alteration 038.2 – Instrumental Activities of Daily Living Alteration	10023410 – Self Care Deficit
R46.0 – Skin Integrity Alteration R46.2 – Skin Integrity Impairment	10001290 – Impaired Skin Integrity

Use of a non-problem (positive) ICNP diagnosis

Among the 169 ICNP nursing diagnoses mapped with CCC problems, a concept "Grief" (10022345) was considered a positive nursing diagnosis/outcome in ICNP but a problem (or negative) nursing diagnosis in CCC. That is, although the CCC concept "Grief" (E53.0) was lexically equivalent to the ICNP concept, the semantic meanings of the concepts were considered to be different based on 'judgment state" of each concept. The two terminology systems defined the 'judgment state' of the concept, "Grief", differently. In the CCC terminology all nursing diagnoses are considered to be problems. In ICNP nursing diagnoses and outcomes (often also used as patient goals) are modeled similarly and each includes a judgment; either positive or negative. In ICNP, "Grief" is judged as normal (or positive): a normal emotion.

Use of lexical and semantic mappings

In only one case it was determined that CCC had a concept with a similar lexical expression as ICNP but was actually mapped to a different concept. Both CCC and ICNP had the concepts "Kinesthetic Alteration" (Q44.3) and "Impaired Kinaesthesia" (10034886). The CCC concept "Kinesthetic Alteration" was mapped to the ICNP concept "Impaired Mobility" (rather than the ICNP concept "Impaired Kinaesthesia"). Again, this mapping was based on semantic definitions of concepts in each terminology.

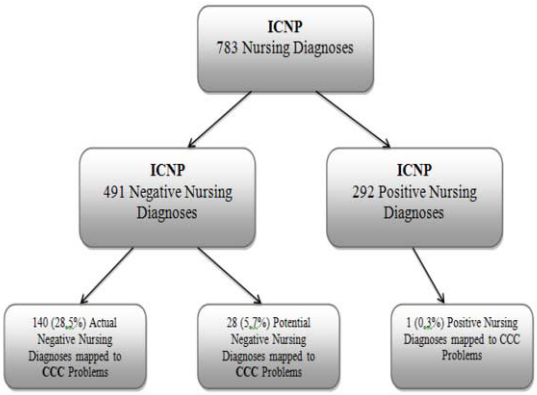

Figure 2 - Results of mappings of nursing diagnoses between CCC and ICNP

Within this study, 25% (44) of the source nursing concepts had identical lexical expressions in the target, 12% (21) had similar lexical expressions and 63% (111) had different lexical expressions, but exact semantic meaning (see Table 3).

Table 3 - Examples of lexical similarities and differences for semantically-equivalent concepts

	CCC Diagnosis	CCC Code	ICNP Diagnosis	ICNP Code
Lexically identical	Fatigue	A01.4	Fatigue	10000695
Lexically similar	Blood Pressure Alteration	C06.1	Altered Blood Pressure	10022954
Lexically different	Spiritual State Alteration	E14.0	Impaired Spiritual Status	10023336

Similarities and difference between two terminologies

Both CCC and ICNP provide a conceptual representation of nursing diagnoses. A major difference in the two terminologies is in the representation of definitions or descriptions of concepts. ICNP is founded on a formal OWL ontology. Definitions for ICNP concepts are represented formally in terms of hierarchical placement and relationships with other concepts. In contrast, each CCC concept has a textual description, but no formal definitions.

Another major difference is that ICNP includes a greater number of nursing diagnoses (n=783) than CCC (n=176). CCC nursing problems are divided between actual negative diagnoses and potential negative diagnoses. ICNP has these, but also includes positive (i.e., 'normal') diagnoses.

A further difference between the two terminologies is that CCC concepts are organised in a conceptual framework. The CCC framework includes 21 Care Components, for example Fluid Volume component (which includes the diagnosis "Electrolyte Imbalance") and Health Behavior Component (which includes the diagnoses of "Noncompliance of Medication Regimen" and "Home Maintenance Alteration"). These CCC Care Components are mutually exclusive, and each of the 176 CCC problems is placed in only one component. The ontological nature and modeling of ICNP allows for multiple parents within the ICNP hierarchy.

These differences present challenges for semantic mapping.

Discussion and Conclusion

This study examined the equivalency mapping between CCC and ICNP negative diagnoses (or problems) concepts. This project moves us closer to a broader harmonisation of nursing content. The mapping of concepts between CCC and ICNP is important in assuring interoperability of data and information across nursing care specialties and settings.

In addition to supporting interoperability among nursing terminologies, ICN also is formally collaborating with IHTSDO to harmonize ICNP and SNOMED CT. As the ICNP is mapped to SNOMED-CT, ICNP-SNOMED CT nursing equivalency tables can be used (together with ICNP-CCC equivalency tables) to automatically generate equivalencies between CCC and SNOMED CT, which will be reported elsewhere. The ongoing harmonisation project between ICNP and SNOMED CT will enhance further interoperability across nursing terminologies and reduce the burden of maintaining multiple, independent equivalency tables.

In addition to contributing to interoperability between nursing and other health terminologies, the findings of this study provided the opportunity to re-examine both CCC and ICNP and make improvements. Specific changes were made to ICNP based on the findings from this study. For example, changes were made to preferred terms in ICNP: "Impaired Ability to Feel" (10022619) was changed to "Impaired Tactile Perception"; "Impaired Ability to See" (10022748) was changed to "Impaired Vision"; and "Depression" (10022402) was changed to "Depressed Mood". These changes better represent both the formal definition and English lexical expression of concepts.

The finding about the concept "Grieving" or "Grief" raises important issues. A complex concept such as "Grieving", may have different judgment states (e.g. normal, risk for problem), depending on the way that the concept is perceived. Leveraging the use of standard terminologies and ontologies in clinical practice requires clarity about the meaning of such concepts.

Both of the terminologies in this study had nursing diagnostic concepts to represent actual problems and potential (risk for) problems. Risk factor identification is especially relevant for nursing practice targeted at health promotion and disease prevention. It is recommended that the significant number of potential problems or risks in ICNP continue to be reviewed and further concepts added based on use cases from nursing practice.

This project aimed to harmonize CCC problems and ICNP nursing diagnostic concepts. While the direction of mapping within the study was from CCC as the source to ICNP as the target, it is interesting to note that the majority (66.8%) of ICNP concepts have no equivalent in CCC. Due to the large number of unmapped ICNP negative nursing diagnoses (n = 323) a new study is underway to examine allocations of these ICNP concepts to the CCC 21 Care Components. Further review of the assignments between ICNP and the 21 Care Components will explore the theoretical organisation of the nursing domain content using the CCC framework [4].

The equivalency table resulting from this project facilitates the interoperability of CCC and ICNP for data exchange and comparison. In addition, CCC data can now be compared to other nursing and healthcare terminologies already harmonized with ICNP.

Abstract

The increasing adoption of Electronic Health Records (EHR) by developing countries comes with the need to develop common terminology standards to assure semantic interoperability. In Kenya, where the Ministry of Health has rolled out an EHR at 646 sites, several challenges have emerged including variable dictionaries across implementations, inability to easily share data across systems, lack of expertise in dictionary management, lack of central coordination and custody of a terminology service, inadequately defined policies and processes, insufficient infrastructure, among others.

A Concept Working Group was constituted to address these challenges. The country settled on a common Kenya data dictionary, initially derived as a subset of the Columbia International eHealth Laboratory (CIEL) / Millennium Villages Project (MVP) dictionary. The initial dictionary scope largely focuses on clinical needs. Processes and policies around dictionary management are being guided by the framework developed by Bakhshi-Raiez et al. Technical and infrastructure-based approaches are also underway to streamline workflow for dictionary management and distribution across implementations. Kenya's approach on comprehensive common dictionary can serve as a model for other countries in similar settings.

Keywords:

Terminology; Electronic Health Records; Concept dictionary; Developing Countries.

Introduction

Developing countries are increasingly adopting information technology applications through the implementation of electronic health records (EHRs) for clinical and managerial activities [1]. This has enabled geographic expansion of access to healthcare, improved data management and reporting, and communication between healthcare providers and their clients [2].

At the heart of each EHR is a concept dictionary, which forms the basis for database organization and semantic interoperability [3]. Concept dictionaries allow the creation of accurate and consistent patient records that can be shared within and across organizations [4]. The use of common terms and concepts in patient records has been shown to enhance the quality of healthcare delivery as numerous decision support systems rely on these terminologies [5].

By their very nature, concept dictionaries are living entities, evolving over time to meet needs within the care organization. Ensuring that dictionaries evolve gracefully usually requires resources and relevant expertise. For a single institution, there are well-defined approaches to assure graceful dictionary management can be achieved [6]. The task however becomes exponentially more complicated when terminologies across multiple institutions have to be semantically interoperable. Dixon et al. succinctly put the problem in context describing the translation of local terminology into available standards as being a complex, costly and resource intensive process [7].

The Unified Medical Language System (UMLS) has allowed the integration of different terminologies without restricting content, structure, or semantics of the original terminologies. This has enabled the creation of mappings among equivalent entities used in different contexts and purposes. This allows semantic interoperability between different terminolgy systems while each evolves to serve its primary purpose [8].

As developing countries start to implement EHRs at scale, they are rapidly running into the issue of assuring semantic interoperability between individual implementations. Unfortunately, clearly defined approaches do not exist to inform how to develop dictionaries to serve multiple implementations within limited resource settings. In most instances, data sharing and system interoperability is only achieved through piecemeal concept mappings. The mappings are often either done between a few local implementations or between a single local implementation's dictionary to multiple standard terminologies [9]. This process is resource intensive and there is often no guarantee that the mappings are accurate [10].

Developing countries with limited resources and few skilled personnel need guidance on approaches that will alleviate the complexity, cost and resource-intensive nature of supporting semantically interoperable dictionaries. In this paper, we describe an approach, taken by Kenya, to come up with a national level concept dictionary to serve multiple EHR implementations across the country. We touch on process, infrastructure, capacity, and foundational issues in creating a national-level concept dictionary that can serve cross cutting needs of clinical care, research, monitoring and evaluation, and reporting. Based on our experience, we outline key principles and approaches that can be used by countries in similar resource-limited settings to comprehensively develop and evolve semantically interoperable dictionaries.

Methods

Setting

Kenya is one of the leading countries in health information technology in Sub-Saharan Africa. Recognizing the important need to manage and use patient data better at the various levels

of care, Kenya's Ministry of Health (MOH) Division of Health Information System developed a Health Information Policy and Strategic plan (2009-2014) [11], and Standards and Guidelines for EHR for the country [12]. After the standardization process was completed, the MOH selected two systems for initial national roll out, namely IQ-Care and KenyaEMR, an adaptation of the open source OpenMRS EHR (http://kenyaemr.org). The MOH also decided that the initial disease foci to be served by these EHR would be HIV, Tuberculosis, and Maternal and Child Health (MCH), with an option to expand to other domains moving forward. Two implementation partners, I-TECH (http://www.go2itech.org/) and Futures Group (http://www.futuresgroup.com/) were selected to implement the selected EHR, and by September 2014, 646 implementations of both systems had been realized at MOH facilities throughout the country.

The national roll out of the two systems occurred in a field that was already increasingly dotted with other EHR implementations. As an example, the Academic Model Providing Access to Healthcare (AMPATH) [13], Kenya Medical Research Institute (KEMRI), and Family AIDS Care and Education Service (FACES), which all offer care services within MOH facilities, already had EHRs with their own local dictionaries.

Challenges

Several challenges related to dictionary management and semantic interoperability quickly became evident in the milieu of multiple EHR implementations. Key challenges included:

- *Inability to share data across EHR:* This example emerged when MOH sites were reorganized to different implementing partners. As an example, it was difficult to easily share data between the Ampath Medical Records System (AMRS) and KenyaEMR systems, despite both being based on the OpenMRS platform due to the different dictionaries in use.
- *Lack of expertise in dictionary management*: With 600 standalone implementations, it was evident that local sites lacked the skill-set to manage dictionaries or new proposed concepts at the local level.
- *Lack of coordination and ownership:* Even when it became clear that a harmonized approach to semantic interoperability was needed across implementations in the country, there were no clear leaders or owners of the problem.
- *Conflict between care, research and reporting needs:* While the MOH aimed to collect data at one reporting level, clinical priorities dictated a higher level of granularity of concepts, while research needs often dictated a broader range of data to be collected beyond what would normally be needed for care or reporting.
- *Lack of policies or processes:* Comprehensive dictionary management requires laid down policies on how to request new concepts, how to make changes to existing dictionaries, and how to prioritize new concept requests for action. In the country, there were big gaps in the relevant policies to guide coordinated management of concept dictionaries.
- *Technical Infrastructure:* The fact that most previously implemented EHRs worked as standalone systems and were not connected to a central server made it difficult to know what the concept needs were at the local level, and also served as a barrier to automatically transmitting concept requests for action centrally.
- *Lack of automated mapping systems:* Even when requests for new concepts could percolate through, their management tended to be largely manual, with deficient mechanisms to automatically map concepts against standardized terminologies.

Approach

Kenya constituted a Concept Dictionary Working group. This working group was made up of 32 individuals with varied but relevant backgrounds, namely: (a) *Healthcare providers* – physicians, clinical officers and nurses; (b) *Data Managers* – Health Records and Health Information Officers, and Monitoring & Evaluation Specialists; (c) *Health Informaticians* - dictionary managers, health system developers and programmers; and (d) *Health Administrators* – MOH County Health Management teams, National EHR implementation coordinators, and program managers.

The Concept Working Group held an in-person meeting between October 29-31, 2014 in Kisumu, Kenya, to define and implement approaches for comprehensive and coordinated national concept dictionary management. This meeting brought together implementing partners and institutions that participate in various healthcare activities as custodians, care providers, information technology solution providers and researchers. Participants were drawn from MOH, I-TECH, AMPATH, KEMRI, FACES, Médecins Sans Frontières (MSF), Elizabeth Glazer Pediatric Aids Foundation (EGPAF), OpenSource Health Management Information System (OpenHMIS) and LakeHUb Kisumu.

The work of the Concept Working Group is largely consultative, but highly informed by well-established lessons, guidance and frameworks around dictionary management.

Results

We describe outcome of the work by Kenya Concept Dictionary initiative, along each of the dimensions outlined in the challenges above.

Common Data Dictionary Considerations

Other than a couple of large institutions in the country, most facilities did not have the skill-set or capacity to create and maintain their own dictionaries. Further, allowing multiple independent dictionaries was already causing interoperability problems. The team recommended that a common national-level concept dictionary be created.

Multiple approaches existed on how to create this common dictionary. Options included:

1. Developing a new dictionary from scratch without influence from existing dictionaries;
2. Taking all existing dictionaries and combining their terms to create a new common dictionary;
3. Using an existing dictionary as the foundation, mapping other dictionaries to it, and evolving it moving forward.

Eventually, the third approach was chosen. This approach is similar to what the Indiana Network for Patient Care (INPC) used when it was coming up with its common dictionary for the Health Information Exchange in the state of Indiana, USA [14]. INPC based its dictionary on the one used by the Regenstrief Medical Record System [15].

It was decided that the Kenya Common Concept Dictionary would be based on the dictionary maintained by Columbia International eHealth Laboratory and the Millennium Villages Project (CIEL/MVP dictionary). The CIEL/MVP dictionary is

already mapped to standard terminology such as SNOMED CT, LOINC, ICD-10, RxNORM and CVX. It also has provisions for Interface Terminology, allowing for easy use within clinical contexts [15]. Given the extensive nature of the CIEL/MVP dictionary, Kenya would only start with those concepts immediately relevant to its needs – these are identified based on clinical needs, relevant MOH forms within the EHR (e.g. MOH 257 – HIV patient care card), previously defined minimum datasets [17], common clinical observations, tests, drugs, procedural observations among others (Figure 1). From this initial subset, some concepts may appear redundant but these will eventually be mapped when future concepts are added as needed. It was also recognized that the CIEL/MVP would not have some terms that would be specific to Kenya, and as such, the Kenyan dictionary would eventually include a small set of its own local terms, but only when these terms were not relevant for incorporation to the larger CIEL/MVP dictionary, and could not be mapped to any other existing vocabulary standard.

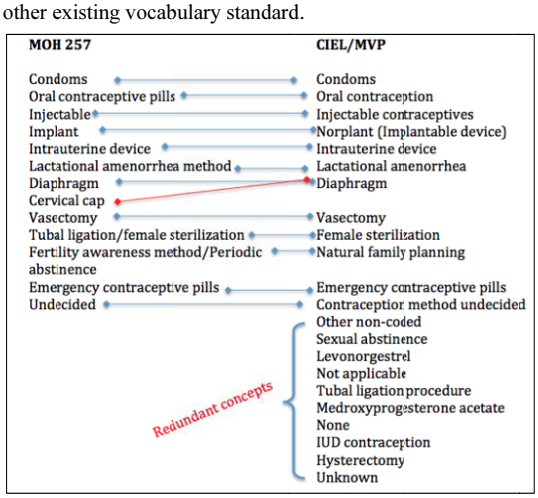

Figure 1: Sample manual mapping of local terms to CIEL/MVP dictionary

Handling conflict between care, research and reporting

A major topic of continued discussion is the scope and granularity level of the Kenya Common Concept Dictionary. There is always tension as to how dictionaries can meet the diverse needs of the various stakeholders, including clinicians, MOH and researchers, among others. Fortunately, Kenya is not the first country faced with this problem. Guidance in this space exist from Chute et al. [18], Cimino's Desiderata [6], and the ISO specifications on terminologies [19]. General recommendations point against creating a single monolithic terminology that attempts to meet all user needs. Instead, terminologies developed should be scoped to serve specific usage categories well [20]. For the case of Kenya, key categories include clinical documentation, administrative, reporting, and research.

Given that EHR being implemented in Kenya are primarily meant to meet clinical needs, a large scope of the Kenya Common Concept Dictionary aims to meet clinical needs. Luckily, key MOH clinical cards (e.g. MOH 257) and registers, which are being replaced by the EHR, already serve the dual purpose of clinical documentation and reporting. We will pay special attention to ensure that we not only have a robust reference terminology, but that it meets interface terminology needs, including appropriate synonyms and multi-lingual functionality. The issues of pre- and post-coordination will continue to be actively considered as the dictionary evolves to meet various needs.

The team recognizes, however, that over time different dictionaries might have to be developed to best serve the various scopes. As an example, a reporting focused dictionary might have concepts that are derivations of multiple concepts in the clinical-targeted dictionary using pre-defined logic. Where appropriate, these dictionaries would also have simple mappings between one other.

Policies and Processes

A core task for the Concept Working Group is to come up with the policies and processes around all aspects of the Kenya Common Concept Dictionary. This organizational aspect of dictionary maintenance is guided by the framework developed by Bakhshi-Raiez et al. [21]. The framework outlines a primary component called 'Execution' which details the various policy and procedural aspects of maintaining a dictionary. Within this framework, criteria and guidelines are provided for submitting new concept proposals, validating them and verifying changes, documentation and version management. In addition to the above, the concept modeling in Kenya is guided by well-established standards for concept creation, curation and evolution [6, 18, 22, 23].

The other components, which support 'Execution', include 'Process Management', 'Change Specifications' and 'Editing Tools'. Under process management, the Concept Working Group has created a team to coordinate its activities, with the custodian institutions being ITECH-Kenya (a leading national EHR implementation) and AMPATH (a large clinical care setting serving a catchment of 3 million people) [24, 25]. Work in progress includes constituting an appropriate maintenance team with procedures to assure responsiveness to requests and creating policies relevant to the dictionary management procedures.

Resources and Human Capacity

Concept dictionary management is resource intensive. The financial support for the Concept Working Group has been provided by the Centers for Disease Control (Grant # U91HA06801). However, extensive resources are still needed to support the executional aspects of this work. Core disciplines that would form the dictionary maintenance team would include user/domain experts, terminology experts, health informaticians, software engineers, coordinators and client support personnel. This formal team has not yet been constituted, and the approach taken so far involves having personnel coming from multiple implementation partners to fulfill these roles. MOH's support and/or custodianship of this initiative would help to assure continued success.

To improve the human capacity to manage dictionaries within the country, special short-courses around Forms, Concepts and Dictionary Management have been conducted by programs such as the Fogarty-funded Regional East African Center for Health Informatics (*REACH-Informatics*) [26]. Emerging programs like the Masters and PhD programs in Health Informatics at Moi University will also have a dedicated coursework that touch on dictionary management - Clinical Decision Support, Ontologies and Workflow (HIC 824). In addition to formal training, the Concept Working Group is leveraging larger informatics networks, especially the OpenMRS community, the OpenHIE Terminology Services [27], the CIEL group, among others to help with various aspects of dictionary maintenance. Implementation partners within the country are also sharing experiences around dictionary management amongst themselves and with the Concept Working Group.

Technical & Infrastructure Consideration

Several technical and infrastructure issues remain relevant to the Kenya Common Concept Dictionary. The dictionary currently does not have a permanent home, with ITECH serving as its custodian. The eventual plan is for the dictionary to be hosted in the National Data Center which is being set up by the Ministry of Health. Software applications still need to be developed to streamline the workflow around concept request, management, mapping and distribution. Mapping, as an example, has remained largely a manual process, with searching done on the Open Concept Lab / Maternal Concept Lab site [28]. In the roadmap for the national concept dictionary is incorporation of semi-automated mapping tools, similar to those employed in other settings and systems [29, 30].

A key technical lesson the country is quickly learning is that EHR implementations that rely on a concept dictionary should not exist without connectivity to a central server. Connectivity is not only essential for health information exchange, but also provides a mechanism for automatically submitting new concept proposals from implementations. Existing approaches to distributing the most current dictionary usually involve emailing of a snapshot, or deployment via SFTP file transfer. Similar to the OpenHIE model, the goal is to eventually be able to deploy the dictionary via API calls from various EHRs.

Discussion

In this paper, we describe efforts by a developing country to implement comprehensive mechanisms for managing concept dictionaries in support of EHR implementations across its MOH facilities. Kenya is not unique in this need. Almost all other developing countries will have similar challenges as they start implementing EHRs at scale. Ideally, countries should anticipate these challenges and needs, and they should put plans for dictionary management in place before glaring challenges emerge. In fact, this issue should be a key focus of initial implementation planning, with countries well advised to appreciate the amount of work and resources required to get it done well. Constituting the right technical working groups, and having appropriate consultations with groups with relevant experience is very important.

Key considerations as outlined in this paper revolve around identifying initial corpus of concepts and assuring that the scope is appropriate for the country's primary needs. Policies and procedures are needed to enable graceful evolution of the dictionary and high quality responsiveness to implementers. Keys to success are the availability of financial resources to support the infrastructure and the right team, recognizing that diverse competencies will be needed. Ideally, the MOH needs to embrace its responsibility as the custodian of this dictionary, and provide the requisite support. This is not to say that the maintenance team has to sit within the MOH, as this responsibility could also be appropriately outsourced to a group that is highly skilled in this area. Capacity building efforts should however be integral to the country's strategy for dictionary management as the responsibilities can require a highly specialized skillset.

Fortunately for developing countries, there is a wealth of resources and research around the optimal approaches for dictionary management for health information exchange semantic interoperability. An appreciation of the core principles, guidelines and frameworks would serve the technical team well [6, 18-20, 22]. Key lessons can also be learned from approaches taken by various Health Information Exchange efforts in the Western world [14]. In addition to consulting developing country partners, countries should also leverage extensive communities around eHealth systems that are working specifically on vocabularies and ontologies. Further, countries are encouraged to share experiences and lessons. Appropriate forums should be constituted to allow these lessons to be shared for multiple levels of stakeholders.

This field is very complex. In fact, there are multiple debates on the optimal approaches to managing dictionaries [31]. The approaches taken by Kenya and presented above might not necessarily be the most optimal in this evolving field. Our team recognizes its limitations, and is willing to adjust direction as needed. The country is also committed to being adaptive and versatile, to assure that it can take advantage of emerging and new approaches to dictionary management. As an example, the OpenHIE Terminology Service is working on a '*Subscription Service*' that would significantly reduce the burden to developing countries in managing concept dictionaries. Kenya's team is already working with this team, and hopes to use this service as needed in managing the Kenya Common Concept Dictionary.

The eventual hope is for countries like Kenya to truly realize truly comprehensive Health Information Exchange systems. The beginning of an Enterprise Health Architecture is starting to be realized in the country, and a comprehensive terminology service would be central to this architecture. In fact, systems like mHealth that are now often implemented in isolation will soon be expected to embrace the same concept dictionary terms that are being used in MOH supported EHR. Obviously, a lot of work remains to help realize the vision of the Kenya Common Concept Dictionary, but the country should be commended for having taken the bold first step in comprehensively addressing the issues around semantic interoperability.

Some of the limitations of this process include the voluntary nature of contributions and participation by individuals and organizations. Required technical and infrastructural supports are not assured. It is hoped that the government can invest more resources and organizations can dedicate more personnel and time in this process.

Conclusion

A Concept Working Group made of multiple stakeholders is leading the evolution of a national level common concept dictionary for Kenya, with close guidance to use well tested approaches for concept dictionary management. The approach by Kenya can be used as a model for other countries hoping to implement terminology based services to support multiple implementations.

Acknowledgments

This work was supported in part by CDC Grant # U91HA06801 and NORAD (Norwegian Agency for Development Cooperation) under the NORHED-Programme , Agreement no. KEN-13/0021. Thanks to the Ministry of Health and Counties for supporting the work of the Concept Working Group and the national EHR rollout. Special thanks go to the following individuals who have been key players in the Concept Working Group: Nicholas Ingosi, Gitahi Ng'ang'a, Kenneth Ochieng, Sara Armson, Petronillah Seurey and Andrew Kanter. We would also like to thank the following organizations for spearheading these efforts and sharing their experiences: I-TECH, KEMRI, FACES, AMPATH and Columbia International eHealth Laboratory and the Millennium Villages Project.

Abstract

The use of Complementary and Alternative Medicine (CAM) is increasingly popular in places like North America and Europe where western medicine is primarily practiced. People are consuming herbal and dietary supplements along with western medications simultaneously. Sometimes, supplements and drugs react with one another via antagonistic or potentiation actions of the drug or supplement resulting in an adverse event. Unfortunately, it is not easy to study drug-supplement interactions without a standard terminology to describe herbal and dietary supplements. This pilot study investigated coverage of supplement databases to one another as well as coverage by the Unified Medical Language System (UMLS) and RxNorm for supplement terms. We found that none of the supplement databases completely covers supplement terms. UMLS, MeSH, SNOMED CT, RxNorm and NDF-RT cover 54%, 40%, 32%, 22% and 14% of supplement concepts, respectively. NDF-RT provides some value for grouping supplements into drug classes. Enhancing our understanding of the gap between the traditional biomedical terminology systems and supplement terms could lead to the development of a comprehensive terminology resources for supplements, and other secondary uses such as better detection and extraction of drug-supplement interactions.

Keywords:

Herbal and nutritional supplements; Complementary and alternative medicine; Biomedical terminology; UMLS; RxNorm.

Introduction

The use of Complementary and Alternative Medicine (CAM) is rising in North America and Europe where conventional western medicine is practiced [1,2]. This is reflected by increasing sales of herbal supplements in the United States and Europe. For example, only 28 percent of women over 60 years in the United States took a Calcium supplement in the early 90s. A decade later, nearly 61 percent of women in that age group were taking Calcium supplements. In the United States, herbal supplement sales have reached an all-time high of 6 billion dollars per year according to a 2013 report published by the American Botanical Council [3]. However, the growing use of supplements is occuring with many adults simultaneously taking prescription medicines. Almost one in six adults in the US taking prescription medicines also takes an herbal supplement [4]. This poses a risk of unintentional interactions between the drug and supplement, especially since documentation is not consistent on supplements [1,3,4]. According to a report published by the Center for Disease Control (CDC), more than half of adults in the U.S take dietary supplements and the use of supplements is on the rise [3]. Fifty-six percent of Europeans are also found to have consumed some form of CAM in 2012 [2]. CAM includes a variety of medical systems, therapies and mind-body interventions. For this paper, we have focused on the subcategory that includes dietary supplements called "biologically based therapies" [1].

Although herbal medicines have gained popularity, knowledge about herbal medicines has not gone up among physicians practicing conventional medicine [4]. In a survey conducted among 1,157 clinicians from around the world, about 75.5 % of them said that doctors are "poorly informed" about herbal medicines. Only 12.9 % said that they always check if their patient is taking herbal medicines before prescribing conventional drugs [5]. There have been some steps to reduce the gap between the use of herbal supplements by consumers and the knowledge of supplements from a clinical perspective.

While herbal supplements are widely believed to be a safe addition to conventional medicines, they can potentially react with western medicine. Herbal and other dietary supplements could increase or antagonize the actions of drugs or they could potentially change pharmacokinetics or pharmacodynamics of the drug or supplement itself [6]. For these reasons, detailed research of drug-supplement interactions is an important area.

In contrast to drug-supplement interactions, drug-drug interactions have been more widely studied and documented. One type of resource leveragd for this, are terminologies which provide a standard and well-defined manner of identifying and describing drugs. For example, RxNorm is a standardized system to describe clinical drugs, developed by the U.S. National Library of Medicine (NLM), which is also the preferred representation of drugs for health information exchange. The brand names, generic names and ingredients are listed along with the relationship between those entities [2,7]. In contrast, there is no well-accepted equivalent for herbal supplements making it more difficult to study drug-supplement interactions. This difficulty creates limitations for studies about drug-supplement interactions and is a substantial barrier for extracting information from the limited existing investigative literature. It is also possible to identify new drug-supplements interactions by extracting information from literature [8] and or collecting through a patient interview [9]. Most studies on drug-supplement interactions focus only on particular known combinations, like cranberry and warfarin, ginkgo and warfarin, or St. John's wort and digoxin [6].

One foundational step towards identifying drug-supplement interactions is establishing a comprehensive terminology system for supplements. This purpose of this paper is to evaluate the supplement term coverage across various online supplements databases. Coverages of the Unified Medical Language System (UMLS) Metathesaurus, Medical Subject Headings (MeSH), Systematized Nomenclature of Medicine--Clinical Terms (SNOMED CT), RxNorm and National Drug

File - Reference Terminology (NDF-RT) for representing supplement terminology were also investigated.

UMLS and MetaMap

UMLS is a repository of biomedical vocabularies, which integrates over 2 million names and concepts. It also contains relationships between concepts and brings together many health and biomedical vocabularies and standards. The UMLS includes the NCBI taxonomy, Gene Ontology, MeSH, Online Mendelian Inheritance in Man (OMIM) and SNOMED CT among over 100 other vocabularies [10].

MetaMap is a Natural Language Processing (NLP) application developed by the U.S. NLM to map biomedical texts to the UMLS Metathesaurus concepts [11]. It is able to tag the text lexically and syntactically and identify the different concept candidates in the UMLS. In this study, MetaMap was implemented to map the supplement terms to UMLS concepts.

RxNorm and NDF-RT

RxNorm is a tool developed by the NLM. It has normalized names for branded and generic drug names. Drug names along with strength, brand names, dosage and ingredient information can be found in RxNorm. RxNorm also supports semantic interoperability between drug names and 15 other drug resources proving additional depth of information related to drugs absent with the UMLS [12].

NDF-RT is a part of the Veteran Health Administration's National Drug file. It is able to classify drugs into formal categories in addition to giving information about their molecular interactions, kinetics, therapeutic categories, and dose forms [13].

Supplement databases

Natural Standard Authority Database (NSAD) is a database set up by Natural Standard, an international research collaboration that reviews scientific literature on CAM. This database is arranged alphabetically and includes Spanish and French in addition to English and Latin names. Each entry includes supplement names in other languages, popular brand names, historical significance of the herb, indications for use, expert opinion on efficacy are all provided with citations from peer-reviewed journals [14].

Medscape is a website with medical content from the WebMD Health Professional Network. The Network strives to provide balanced, accurate health information. They provide information written by physicians and other authorities on particular topics making information from Medscape relatively reliable [15].

Natural Medicines Comprehensive Database (NMCD) is a database of nature-based medicines and alternative therapies managed by the therapeutic research center, composed of a panel of pharmacists and clinicians. The panel is not affiliated with any pharmaceutical company, and their work is intended to be useful for pharmacists and clinicians. The website is updated regularly and incorporates the latest research. The database has terms enabling term searches in several Asian and European languages, by botanical names and by common names. Under each plant substance, the effectiveness of the plant, safety, known interactions, mechanism of action, and adverse reactions are listed. There is an application with NMCD that allows users to search for interactions between a drug and a supplement. NMCD is aimed at professional clinicians or pharmacists and may not be easy to understand for a layperson [16].

MedlinePlus is the U.S. National Institute of Health's website for the general public. The website is produced by the NLM and has information about diseases, conditions, health care issues drugs and supplements. The information in the database is available from the U.S. National Center for Complementary and Integrative Health (NCCIH). All statements are supported by evidence from peer-reviewed literature. Supplement names in languages other than English are not available for search. For this study, we only used information from the website on herbs and supplements [17].

Drugs.com is a website that aims to provide consumers with health, drugs and supplement-related information. Information is sourced from Harvard Health publications and Wolters Kluwer Health. Drugs.com provides indications, possible side effects, and interactions with other drugs.It is targeted at lay consumers and provided in a user-friendly format. The website also provides a platform for users to discuss with one another about the drugs. Having only 66 supplements, this was our shortest resource of supplements [18].

Methods

Comparison supplement terms coverages

We compared the supplement term coverage between all five databases in a several step process, as illustrated in Figure 1.

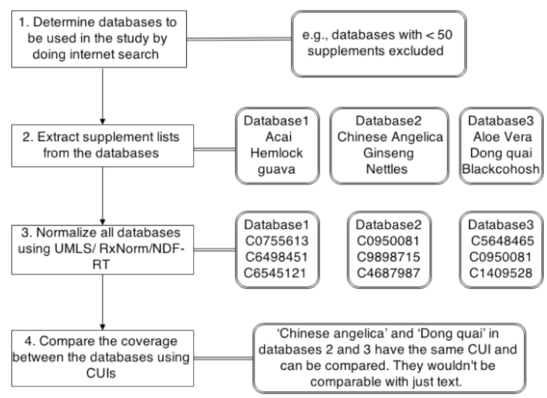

Figure 1 - Illustration of method to compare supplement terms across five online databases

Step 1: Determine the databases to be included in the study. An Internet search was performed for the top herbal supplement databases to identify the included databases. The top results were then subject to further exclusion criteria. If databases were not based on evidence-based science, they were rejected. For example, Holistic heart health, Healthline and WebMD's databases were rejected for not having peer-reviewed sources. Databases with very few (<50) supplements were also rejected. Also one other database on the Dr. Oz's website was no longer available, so that was excluded as well. Rxlist was also rejected since it merely mirrored NMCD's list. Finally, the supplements were obtained from each qualified resource website: NSAD, NMCD, MedlinePlus, Medscape, and drugs.com.

Step 2: Extract supplements from databases. We extracted supplement terms from online databases and used these in our further analysis. We manually removed redundant non-English terms from the list of NSAD while keeping their corresponding English names.

Step 3: *Normalize supplements using UMLS, MeSH and SNOMED CT*. To normalize supplement terms between different databases, supplements were first mapped to UMLS

Concept Unique Identifiers (CUIs) by using MetaMap – which then provides common meanings for the different sources of supplements. Only exact mapping with a score of 1000 were retained. Manual cleanup was performed to remove irrelevant mapping candidates. Semantic types such as 'gene' or 'geographical area' were eliminated before comparing the coverage between different databases. Irrelevant concepts after mapping were also excluded by manual review. When multiple CUIs were returned by MetaMap, the most accurate CUIs were retained. For example, when multiple CUIs were found for a single term, the CUI corresponding to semantic type "plants" was retained over "extracts". Supplement terms were also mapped to MeSH and SNOMED by restricting the terminology source in MetaMap in an effort to use multiple sources to normalize the databases.

Step 4: Compare the coverage between the different databases. Before mapping, we first implemented exact match for supplement terms and analyzed how frequent an individual term exists in each database. UMLS CUIs were then used to compare the coverage of supplements between five databases. We further generate a Venn diagram showing the coverage across databases using UMLS. After integrating concepts from all databases into a full list, we also grouped UMLS concepts based on their semantic types.

Analysis of supplements representation in RxNorm and NDF-RT

To further investigate how RxNorm and NDF-RT represent supplements, we first used RxMix functions to map terms of each database to RxNorm and NDF-RT concepts. RxMix is an NLM developed tool to allow users to combine all functions of RxNorm, RxTerms, and NDF-RT [19]. We then integrated all mapped RxNorm concepts into a respective list. To further investigate the detailed drug class information, we used RxMix to analyze the integrated RxNorm concept list from all databases. Specifically, we created such a workflow to identify the VA drug class for a given supplements string:

$$RxNorm : findRxcuiBySting \rightarrow RxNorm : getRelatedByType \rightarrow NDF-RT : findConceptsByID \rightarrow NDF-RT : getVaClassOfConcept$$

Results

The first part of this study compared supplement terms without referring to any standard terminology source to investigate if any of the databases are able to cover all the supplements from the pooled lists of the databases. Figure 2 shows the frequency in which a particular supplement is found across the 5 databases. Without any term normalization, very few supplements are found across all five databases, but about 2,500 terms appeared in only one of databases.

To compare supplement term coverage across five databases, we normalized terms by using UMLS, MeSH, SNOMED CT, RxNorm, or NDF-RT source. The number of terms mapped to various sources from each database is shown in Table 1. In general, UMLS has the largest coverage for the supplements, and MeSH and SNOMED CT cover more supplement terms than RxNorm and NDF-RT. For example, the largest database NSAD had 1,331 total terms extracted from the website resulting in 1,088 UMLS concepts, 565 RxNorm concepts and 348 NDF-RT concepts with mapping. NMCD had a higher percentage coverage (78%) by UMLS concepts. MedlinePlus and Drugs.com were also covered well by all terminology sources. After integrating supplement terms from different databases into a comprehensive list, we obtained 3,115 unique terms, resulting in 1,683 UMLS, 1,257 MeSH, 984 SNOMED CT, 677 RxNorm, and 422 NDF-RT concepts. Clearly, none of these terminologies can fully represent supplement terms.

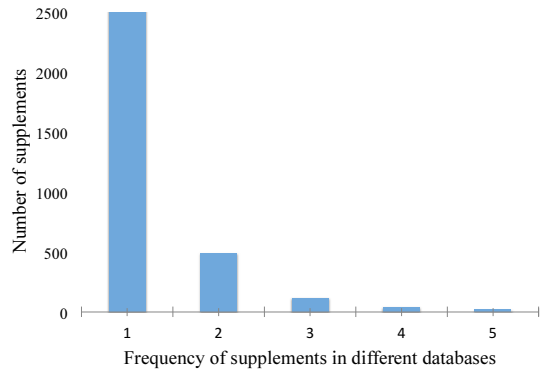

Figure 2 - Frequency of supplement terms across databases

Table 1 – Number of supplement terms mapped to the UMLS, MeSH, SNOMED CT, RxNorm and NDF-RT concepts

	NSAD	NMCD	MedScape	Medline	Drugs
Terms	1331	1038	1080	134	66
UMLS	1088	810	398	121	65
MeSH	930	658	307	108	49
SNOMED	669	492	291	99	41
RxNorm	565	400	228	93	60
NDF-RT	348	272	124	75	43

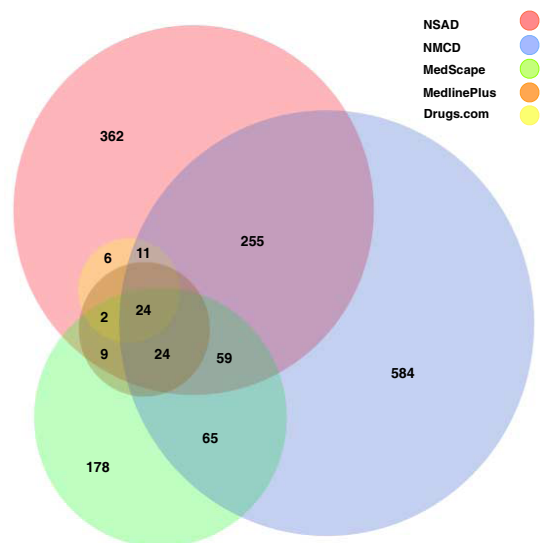

Figure 3 – Venn diagram of UMLS concepts for supplements across five databases

Figure 3 shows a Venn diagram of supplements concepts from the 5 databases after mapping to UMLS concepts. Twenty-four concepts are common to the 5 databases. All five databases have unique CUIs and different coverage with other databases. Not even the largest among the five databases is able to cover a large percentage of terms comprehensively.

After analyzing the semantic types in UMLS concepts, we found that 34% of concepts are plants (*e.g.*, cat's claw, comfrey, damiana), and 18% are organic chemicals (Table 2). Many concepts belong to multiple semantic types, such as Aloe vera, which is a plant, a pharmacologic substance and an organic chemical. About 5% of concepts were classified as food.

Table 2 – Top semantic types of UMLS concepts for supplements

Semantic type	Percentage
Plant	34%
Pharmacologic Substance	27%
Organic Chemical	18%
Food	5%
Biologically Active Substance	4%
Element, Ion, or Isotope	2%
Vitamin	2%

With the aid of the tool RxMix, we found several drug classes for about 300 supplements (about 43% of mapped RxNorm concepts), some of which are listed in Table 3. Not surprisingly, multivitamins were the largest class for supplements. Some other classes, including stimulant laxatives, emollients, antihypoglycemics, antivertigo agents, genito-urinary agents, were also found. Since supplements in the same group can have similar properties, this help to investigate drug functions, adverse effects and interactions with other drugs.

Table 3 – VA drug Class for supplements in NDF-RT

Drug class	Examples
MULTIVITAMINS	alpha-tocopherol,biotin, coenzyme, cyanocobalamin, dexpanthenol, ergocalciferol, folic acid, l-ascorbic acid, niacin, nicotinamide, pantothenol, phytonadione, pteroylglutamic acid, pyridoxine, retinol, riboflavin, thiamine
STIMULANT LAXATIVES	Aloe, cascara, cascara sagrada, castor oil, senna
RESPIRATORY AGENTS,OTHER	Camphor, eucalyptus oil, sodium chloride, turpentine oil
PANTOTHENIC ACID	Dexpanthenol, pantothenic acid, pantothenol, Vitamin B5
EMOLLIENTS	aloe vera, glycerol, retinol, vitamin A, vitamin E
HERBS/ALTERNATIVE THERAPIES	docosahexaenoic acid, eicosapentaenoic acid, ginkgo, ginkgo biloba, inositol, l-methionine, methionine, vitamin E
GENITO-URINARY AGENTS,OTHER	dimethyl sulfoxide, povidone-iodine, yocon, yohimbe, yohimbine

Discussion

This study examines the problem of a lack of standard terminology in describing herbal and dietary supplements. This is a significant problem because herbal supplements may interact with prescription medicines leading to potentially harmful interactions. Without a standardized terminology, studies and comparative research become more difficult, as well as other knowledge-sharing related to supplements.

Although many supplements and their interactions with drugs are published online, they usually use different names and focus on different entities. We found that all databases we examined had substantial gaps. The low degree of supplement terms commonality does create difficulty in utilizing a single database source for supplement study development and evaluation at present. A combined resource approach is likely needed for robust supplement term identification.

Many of the supplement terms could not be mapped to UMLS Metatheasurus. On review of some of the unmapped terms a number of findings were noted. Unlike traditional medications which typically have a generic and trade name and a chemical identifier, the dietary supplements are more complicated especially plant products. Starting with Latin Genus and Species information a particular supplement may have multiple common names depending on where the product is grown and the ultimate supplement consumer. Several common supplements had five of more common names making it challenging to map the name to a single entity. Several exact matchs were also identified as irrelevant mappings. For example, cartilage (bovine and shark) was mapped to "1000 C0007301 Cartilage [Tissue]".

In addition, particular supplements may have different names based on qualifiers for the country of origin or the part of the plant which was used. Some products may have different reference names based on whether it was prepared by some means such as an extract which chemically is similar to the parent supplement but may be changed in some way after preparation. Arguably this may reflect more a dosage change in some cases but will vary on the supplement and the preparation method. Incorporation of the common preparation methods for supplement products may need additional exploration to identify the appropriate standards to accurately reflect the supplement being reviewed.

The number of concepts retrieved by the MetaMap application is much lower than the number of supplements in the NSAD and Medscape databases. One reason is that the MetaMap was also unable to map some chemical names (e.g., 1,3,7-trimethyl-2,6-dioxopurine). Another reason for the observed limited performance of MetaMap is that we restricted matches to exact mapping with a score of 1000. Some concepts with a lower score were therefore excluded. For example, "new zealand green-lipped mussel" was mapped to two UMLS concepts "933 NEW ZEALAND GREEN MUSSEL (New Zealand green mussel extract) [Organic Chemical, Pharmacologic Substance]" and "637 lipped (Lip structure) [Body Part, Organ, or Organ Component]". Another example is a combination of herbs that are available as a single supplement listing – for example, "bilberry/evening primrose/flax", which did not exactly map to any single concept. After manually reviewing those with lower mapping scores (<1000), we found additional 15, 20 and 31 correct mappings for NMCD, NSAD and Medscape, respectively. It was also found that UMLS doesn't have a trinomial classification of plants, making the CUIs less specific. For example, ginseng from different countries (*e.g.*, Chinese gingseng and Korean ginseng) were mapped to the same CUI with outputs as "1000 C0949314: Chinese ginseng (*Panax ginseng*) [Plant]" and "1000 C0949314: Korean ginseng (*Panax ginseng*) [Plant]". Both "ginseng, American" and "ginseng, siberian" were mapped to "C0949314 ginseng (*Panax ginseng*)". In practice, ginseng from different geographical areas is used for different purposes and may have

potentially different active supplement concentrations – arguing for classifying these under different concepts. UMLS perhaps lacks the depth needed to represent herbal supplements. Also, some of the databases used in this study had repetitions containing the same herb in different languages. Place of supplement origin is unique for herbal substances. Such geographic origin information sometimes can be recognized by the supplements names. For example, ma huang has the botanical name *Ephedra sinica* where sinica stands for China. There is another species of Ephedra called *Ephedra funerea* named for the funeral mountains in the United States. Although UMLS had a broader coverage of supplement concepts, RxNorm and NDF-RT, as part of UMLS, can provide more detailed information about medications, including brand and generic name, dosage, drug class and interactions, which is useful for finding relationships between supplements. Future inclusion of additional supplements into these resources and frameworks will have significant value for secondary uses of supplement information. Our study has a number of limitations. One limitation is the use of only five databases, all of which are based in North America. A more comprehensive study would include more databases from geographically diverse sources. While the MetaMap system is accurate, the application is limited to English terms only, and only exact matches were included in this study, resulting in a large number of terms that did not map. The Anatomical Therapeutic Chemical (ATC) classification system [20] devloped by the World Health Organization is another terminology we plan to evaluate the supplements term coverage. Future research will also focus on integrating knowledge resources to form a more comprehensive system of terminology for describing herbal and dietary supplements.

Conclusion

This pilot study compared supplements across five popular online herbal supplement databases. None of the databases were found to be comprehensive enough to represent a large majority overall of supplements in these resources. Analysis of the coverage of UMLS, MeSH, SNOMED CT, RxNorm and NDF-RT for describing herbal and dietary supplements demonstrated that UMLS covered over half (54%) of the supplements extacted and integrated from five databases. RxNorm and NDF-RT contain more detailed drug-related information, including drug classes for some supplements. This study is important because it provides insights on current gaps and potential opportunities to enhance our understanding of how different terminologies can be used to represent herbal supplements.

Abstract

Due to fundamental differences in design and editorial policies, semantic interoperability between two de facto standard terminologies in the healthcare domain – the International Classification of Diseases (ICD) and SNOMED CT (SCT), requires combining two different approaches: (i) axiom-based, which states logically what is universally true, using an ontology language such as OWL; (ii) rule-based, expressed as queries on the axiom-based knowledge. We present the ICD–SCT harmonization process including: a) a new architecture for ICD-11, b) a protocol for the semantic alignment of ICD and SCT, and c) preliminary results of the alignment applied to more than half the domain currently covered by the draft ICD-11.

Keywords:

ICD, SNOMED CT, Standards, Ontology, Terminology, Classification.

Introduction

The project to achieve semantic alignment between these two standards in the healthcare clinical vocabulary began with an agreement signed in 2010 between the World Health Organization (WHO) and the International Health Terminology Standards Development Organization (IHTSDO). ICD[1], currently published as ICD-10, is the most important worldwide standard for mortality and morbidity statistics. However, it is is also used – in several national modifications and extensions – for health care documentation and billing. The international clinical terminology standard SCT[2,3] has been expanding under the management of the IHTSDO. SCT promises to provide an international standard for codes, terms and formalisms to represent details of the health care process.

The current ICD – SCT alignment efforts occur at a time when clinicians, documentation specialists, epidemiologists, health care administrators and health service researchers identify more and more use cases in which SCT is used in parallel with ICD and local procedure and medication terminology systems. This alignment is driven by requirements for increasing granularity of clinical content to record expanding medical knowledge arising from genomic and related research. To ensure full semantic interoperability between ICD and SCT, a semantic alignment policy was developed which relates ICD classes to rule-based queries depending upon an ICD-11–SCT Common Ontology (CO) [4]. Here we report on the current state of this harmonization effort.

This harmonization requires an innovative architecture for ICD-11 because, in the past, the two standards have been based on different semantics: SCT on axioms that express universal truths (e.g. that all instances of *Thrombosis* affect the vascular system); ICD on rule-based knowledge that introduce class definition (e.g. thrombosis in pregnancy falls into a different class for public health reporting).

Materials and Methods

ICD-11 – SCT Harmonization

In 2007, the WHO launched the revision of ICD[5]. After the agreement between WHO and IHTSDO, a Joint Advisory Group (JAG) was established in 2010. There was consensus within JAG that the harmonization could not simply be a mapping between representational entities (classes and concepts) of both systems. The consensus approach was to base the alignment around a Common Ontology following widely acknowledged principles [6-10].

ICD-11 was designed as a multi-component architecture[4]. The first component is a set of "linearizations" for different uses cases – mortality, morbidity, primary care – that are organised as a single hierarchy with disjoint, exhaustive classes taking origin in previous versions of ICD. A second component, named the Foundation Component (FC), contains all of the ICD-11 classes organised according to new, more flexible principles.

This foundation component has at its core, a model of meaning based on description logic [11], using formalisms and language equivalent to those of the semantic web community deployed in OWL[12] and SNOMED CT. This model was named the ICD – SCT Common Ontology (CO)[4, 13]. Fig. 1 illustrates how the common ontology is related to: (i) SNOMED CT, (ii) ICD-11 linearizations and (iii) contingent

knowledge in the ICD content model, such as diagnostic criteria or therapies, originating with WHO class definitions.

The Common Ontology is a subset of the international release of SNOMED CT (hereafter abbreviated to "SNOMED") expanded and revised for ICD convergence. The Common Ontology has been harmonized with ICD text definitions supplied by the WHO. The CO drew primarily from SNOMED *Clinical Findings* hierarchy, which includes findings, disorders and diseases. The CO has minor components from other SNOMED hierarchies including *Situations*, *Events* and *Social context* and will have defining attributes taken from *Body Structure, Organisms, Physical agents* and others.

JAG had concluded during convergence discussions that these concepts denote clinical situations, i.e. phases of a patient's life, in which a given condition of clinical relevance is present [14].

The ICD class definitions and metadata were assembled using the ICD URI API[15, 16]. SNOMED normal forms and definitions were provided by IHTSDO from the 2015-01-30 international release. The two terminologies were lexically mapped and managed with an Equivalence Table (ET), which was the worksheet for semantic analysis as described below. A Sequel Pro API was used by the IHTSDO to interface with a DL classified developmental version of SNOMED.

This ET contained stated normal forms of pre-coordinated concepts as well as proposed additions to SNOMED. Referential quality assurance rules ensured consistency between chapters and tracked changes to SNOMED across developmental releases.

The architecture of the system was built around a web-accessible MySQL ET data base that could be fed with Excel files or SQL. The database could generate output in any of these modes or as an OWL file [17]. The database is synchronised with IHTSDO equivalence matching tools using a customized exchange format. In this database, we used a double browser (ICD-11/SNOMED) with graphical interface connected by equivalences links.

The web application was able to maintain multiple equivalences, recorded by author, in order to also study inter-observer agreement in equivalence identification. When testing semantic alignment required reclassification of the common ontology, we exported an OWL version to Protégé [18] for description logic classification and comparison of inheritance.

Methods for semantic alignment

1 For a defined subset of ICD beta foundation hierarchy (roughly equivalent to a chapter in ICD-10), generate a candidate map from ICD-11 classes to concepts in "Clinical findings", "Situations", "Events" or "Social context" branches of the SNOMED hierarchy. To identify the map, consider the SNOMED fully specified name (FSN), ICD short text definition, the SNOMED logical definition, and the SNOMED Short Normal Form. (Class M, Table1)

2 For ICD-11 classes without corresponding SNOMED content, mark as Unmatched (U). Develop when possible a candidate pre-coordinated SNOMED concept node to be added to core. Use the new SNOMED concept's normal form as the Common Ontology (CO) concept. (class U/A see Table 1)

3 If ICD class is too complex for a single or pre-coordinated SNOMED concept, try to express the ICD 11 class as a Boolean Logical expression within the constraints of SNOMED model of meaning. Identify the expression as the CO entry. (class U/E, Table 1)

4 Bypass ICD-11 residual classes (NEC) but check if there is a broader match (Parent) (Class U/R, Table 1)

5 If none of the above is possible, propose added SNOMED attributes (U/X, Table 1) or new attribute values (U/EX, Table 1) to create the CO concept.

Table 1– Types of match of ICD Common Ontology concepts to SNOMED CT (SCT)

Match Type & Meaning	**Action in SNOMED**	**Common Ontology Axiom**
Match (M)	–	SCT Short Normal Form
Unmatched/A (U/A)	Add appropriate pre-coordinated concept to SCT	New SCT precoordinated Normal Form
Unmatched/E (U/E)	Post-coordinated expression without change in the model of meaning	SCT post-coordinated Logical expressions
Unmatched/R (U/R)		None
Unmatched/X (U/X)	Potential to add with change to SCT model of meaning	Discussion with IHTSDO
Unmatched /EX	Potential to add with change to content model-object/value	Discussion with IHTSDO

Table 1 summarizes the different types of SNOMED (SCT) candidate matches to Common Ontology

6 For each pair of ICD-11 class/subclass and SNOMED concept in the equivalence table: a) check the WHO short text definition for content, consistency and meaning; b) check the semantics of the SNOMED concept or expression including FSN and description logic (DL) definition (short normal form) to assess the alignment of the meanings of the ICD and SNOMED definitions; c) flag all discrepancies and send them to the WHO/IHTSDO interdisciplinary team for:

a) modification of ICD-11 text definition by a Joint Advisory Group definitions workgroup, or

b) changes to SNOMED description logic definition by SNOMED editors

7 For revisions to SNOMED concept definitions, recompile the DL classification of the edited SNOMED content including expressions (U/E). From the reclassified SNOMED, enumerate the set of all subsumed SNOMED concepts corresponding to each equivalent ICD-11 class and assure that the subsumed set has a one-to-one match within the set of subsumed SNOMED mapped concepts and expressions. Identify discrepancies between the subsumed sets.

8 Evaluate the discrepant class/concept pairs for FSN and logic definitions and determine the root cause of the mismatch. Is this is a misalignment of the ICD-11 subclass with the definition of the ICD-11 class or a difference in concept or attribute definition in SNOMED?

Submit the discrepancies to an interdisciplinary team to identify the root cause and propose:

a) JAG workgroup to revise ICD-11 class definition

b) IHTSDO Editorial staff to revise or expand SNOMED content

9 After resolution of all issues in this chapter of ICD-11, return to step 1 for analysis of next domain.

Results

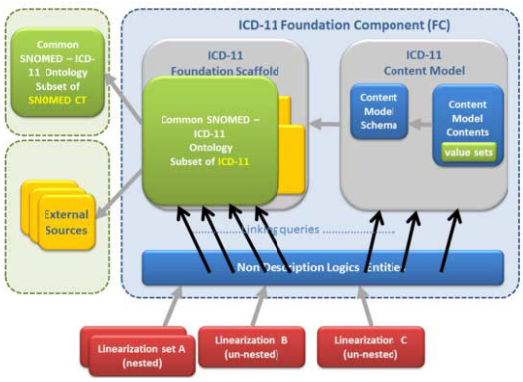

Figure 1 – Architecture of the new ICD-11 architecture and its relationship to SNOMED CT

Updated architecture

Figure 1 is a graphical representation of the new ICD-11 architecture. The outer light blue box represents the Foundation Component (FC), which contains all of the ICD-11 classes or entities, regardless of source. The two smaller boxes on the left represent the external sources for concepts, primarily SNOMED. The Common Ontology is shown in green, a subset of SNOMED participating in ICD-11.

Linearizations are shown in red below the Foundation Component. Each code in each linearization points to a "non-DL entity" in the Foundation Component (FC) whose meaning in terms of the Ontology Component is expressed in a linking query referencing the Ontology Component.

Additional facts about the entities in the Foundation Component are contained in the Content Model. These might include signs and symptoms of diseases, indications and contraindications of drugs among many. These facts are "contingent" (or in traditional philosophical language "particular") rather than universal. That is, they are usually true, or true under certain conditions, but not necessarily "true by definition".

Semantic alignment

The semantic alignment process is ongoing; to date: 16 751 classes/subclasses of the ICD-11 Foundation component have been studied from approximately 39,000 entities (42,9%) .

Table 2 summarizes the percentage of each ICD-11 chapter that has been analysed.

Tables 3, 4 and 5 provide examples of semantic alignment activities to date.

Table 6 presents the summary results of match types for the portion of ICD-11 evaluated thus far.

Table 2– Semantic alignment by ICD-11 chapter (percentage on 01-01-2015)

Chapter	(%)
Infectious diseases	90%
Diseases of the blood and blood-forming organs	30%
Endocrine, nutritional and metabolic diseases	55%
Diseases of the ear and mastoid process	60%
Diseases of the circulatory system	100%
Diseases of the respiratory system	100%
Diseases of the digestive system	100%
Diseases of the skin	80%
Diseases of the musculoskeletal system and connective tissue	90%
Diseases of the genitourinary system	100%
Pregnancy, childbirth and the puerperium	100%
Certain conditions originating in the perinatal and neonatal period	100%

Table 3– Exact match examples

ICD11 Rubric	Common Ontology (Short Normal Form)
Cerebral venous thrombosis	95464572001|Disease (disorder)|:{116676008|Associated morphology (attribute)|=396339007|Thrombus (morphologic abnormality)|363698007|Finding site (attribute)|=68351006|Structure of cerebral vein (body structure)|}
Coronary vaso spastic disease with angina	194828000|Angina (disorder)|+23687008|Coronary artery spasm (disorder)|:{363698007|Finding site (attribute)|=74281007|Myocardium structure (body structure)|}

Discussion

The overall results show that among 16,751 ICD-11 FC entities 14,348 (85.5%) (Table 6) can be represented by the SCT model of meaning either directly or through a pre-coordinated/post–coordinated alignment between the two systems. Very few are residuals which have to be cleaned from the FC or need a revision of SCT formal model of meaning. We propose three examples (Tables 3, 4 and 5) to show how the two systems share the same universal knowledge and how they differ in their contingent knowledge:

1. The defining relationships of SNOMED allow the full representation that can be used for both the ICD-11 Foundation Component class and the SNOMED concept. For example, the ICD Foundation Component entity, "Coronary vaso-spastic disease with angina", is necessarily and sufficiently defined by SNOMED "87343002 | Prinzmetal angina (disorder)".
2. The SNOMED defining relationships do not provide a complete ontological representation of both entities in a single SNOMED concept, in which case the concept model or pre-coordinated SNOMED content must be

Table 4– Pre coordination examples

ICD-11 Rubric	Common Ontology
Aldosterone-producing carcinoma	FSN Primary hyperaldosteronism due to aldosterone-secreting malignant neoplasm of adrenal gland (disorder) Short Normal Form 116680003 | Is a |88213004 | Hyperaldosteronism, |42752001 | Due to|255035007 | Adrenal carcinoma|
Acute myocardial infarction, STEMI, anterior wall	FSN Acute ST segment elevation myocardial infarction of anterior wall(disorder) Short Normal Form 401303003 | Acute ST segment elevation myocardial infarction | + 54329005 | Acute anterior myocardial infarction

Table 5– Post coordination examples

ICD-11 Rubric	Common Ontology
Asymptomatic stenosis of extracranial carotid artery	116680003 | Is a |230738008 | Asymptomatic cerebrovascular disease, |363698007 | Finding site|17999001 | Structure of cervical portion of internal carotid artery, |116676008 | Associated morphology|415582006 | Stenosis
Internal auditory artery occlusion	116680003 | Is a |2929001 | Occlusion of artery, |363698007 | Finding site|89471000 | Structure of labyrinthine artery

expanded. An Example is ICD-11 "Acute myocardial infarction, STEMI anterior wall" that can only be represented in SNOMED by pre-coordinating "401303003 |Acute ST segment elevation myocardial infarction (disorder)" with "54329005 | Acute anterior myocardial infarction".

Conclusion

The essence of the ICD-11 SCT semantic alignment is the establishment of a SNOMED subset with its logical or model of meaning representation that precisely formalizes the meaning of the content of the ICD-11 Foundation Component, following principles of formal ontology and logic *i.e.* that is restricted to axioms that express universal truths in terms of SNOMED concepts. This is clearly distinguished from the ICD content model on the one hand, which represents contingent knowledge at the level of Foundation Component entities, and the rules base (Fig. 1, "non-DL entities"), that cannot be expressed directly in the SNOMED compositional grammar (or any similar logical formalism) and which contains queries on the common ontology that assure the disjointness principle in the linearizations created out of them.

Thus, all content of ICD-11, the semantic standard for health statistics in mortality, morbidity, primary care documentation and billing, will be linked to SCT, the most fine grained medical terminology system, each of which keeps its own profile as a distinct terminology artifact.

Table 6– Match types overall results

Match Type	Number	Common Ontology
Match M	8354 (49.8%)	SCT Short Normal Form
U/A	4933 (29.4%)	To be developped with SCT grammar and pre-coordination
U/E	1061 (6.3%)	To be developped with SCT grammar and post coordination
U/R	1487 (8.8%)	Navigational/residual concepts
U/X and U/EX	916 (5.4%)	Requires clarification

This will require certain refinement and redesign efforts increasing the quality on both ICD-11 and SNOMED, but this is an advantage in itself. When finished, users will have at their disposal two semantically interoperable terminology systems, each tuned for its specific purposes. In the longer term, sharing the maintenance between WHO and the SNOMED authority, IHTSDO, will ease the introduction of new knowledge sources into the heathcare community.

Further on, this common ontology shall be used for the maintenance of all of the existing WHO ICD as well as the ICD-(10/11) national modifications, thereby easing international comparisons and backward compatibility with current systems.

Acknowledgments

This work was supported by the World Health Organization (WHO) and the International Health Terminology Standards Development Organization (IHTSDO) through their Joint Advisory Group (JAG).

Abstract

***Objectives**: To extend the coverage of phenotypes in SNOMED CT through post-coordination. **Methods**: We identify frequent modifiers in terms from the Human Phenotype Ontology (HPO), which we associate with templates for post-coordinated expressions in SNOMED CT. **Results**: We identified 176 modifiers, created 12 templates, and generated 1,617 post-coordinated expressions. **Conclusions**: Through this novel approach, we can increase the current number of mappings by 50%.*

Keywords:
phenotype; SNOMED CT; ontology; post coordination

Introduction

While the usefulness of coarse phenotyping based on electronic health record (EHR) data has been demonstrated in the context of recent genomic studies (e.g., [1]), the study of rare syndromes requires detailed phenotyping. More generally, deep phenotyping is required in order to understand how genetic variation relates to clinical manifestations [2]. Despite efforts to facilitate the adoption of standards for phenotyping across domains (e.g., PhenX project [3]), resources for phenotyping tend to vary between clinical data repositories used for translational research and in healthcare settings. For example, while somewhat overlapping, the Human Phenotype Ontology (HPO) used for annotation of research data and SNOMED CT used in EHRs have not been developed in a coordinated fashion and are only partially interoperable.

In previous work, we assessed the coverage of HPO terms in standard terminologies using simple lexical mapping through the UMLS [4]. Only 54% of HPO classes mapped to UMLS concepts and only 30% mapped to SNOMED CT. This simple approach only considered mapping to pre-coordinated terms in SNOMED CT. However, in addition to the pre-coordinated terms distributed with the terminology, SNOMED CT supports the creation of post-coordinated expressions, i.e., logical definitions based on the SNOMED CT concept model. The examination of HPO terms with no lexical mapping to SNOMED CT reveals that they can often be decomposed into simple elements, which could be mapped to SNOMED CT and aggregated into post-coordinated expressions.

For example, the HPO term "Renal Hypoplasia" [HPO:HP_0000089] maps to the (pre-coordinated) SNOMED CT concept "Congenital hypoplasia of kidney" [SCTID:32659003]), with synonym "Renal Hypoplasia". In contrast, there is no pre-coordinated concept in SNOMED CT for the HPO term "Macular hypoplasia" [HPO:HP_0001104].

However, as shown with "Congenital hypoplasia of kidney", the notion of congenital hypoplasia can be represented in SNOMED CT, which also provides a concept for the anatomical structure "Macula lutea structure" [SCTID:82859000]. Therefore, it is possible to create a post-coordinated expression for "Macular hypoplasia", using the template provided by "Congenital hypoplasia of kidney".

The main objective of this work is to extend the coverage of phenotypes in SNOMED CT through post-coordination, i.e., beyond simple lexical mapping to pre-coordinated terms. More specifically, we remove various types of modifiers in HPO terms in order to decompose them into semantic elements that can be recomposed into SNOMED CT expressions through post-coordination. We demonstrate that we can increase the current number of mappings by 50%.

Background

HPO. The Human Phenotype Ontology (HPO) is an ontology of phenotypic abnormalities, used for the annotation of databases such as OMIM (Online Mendelian inheritance in Man), Orphanet (knowledge base about rare diseases), and DECIPHER (RNAi screening project) [5]. The version of HPO used in this investigation is the (stable) OWL version downloaded on April 16, 2014 from the HPO website. It contains 10,491 classes and 16,414 names for phenotypes, including 5,923 exact synonyms, in addition to one preferred term for each class.

SNOMED CT. Developed by the International Health Terminology Standard Development Organization (IHTSDO), SNOMED CT is the world's largest clinical terminology and provides broad coverage of clinical medicine, including findings, diseases, and procedures for use in electronic medical records [6]. It is implemented with a description logic backend and supports two types of concepts. Pre-coordinated concepts are named and defined in SNOMED CT. Post-coordinated concepts are made up of other concepts in a compositional approach [7]. The U.S. edition of SNOMED CT dated September 2013 is used in this work.

UMLS. The Unified Medical Language System (UMLS) is a terminology integration system developed by the U.S. National Library of Medicine [8]. The UMLS Metathesaurus integrates many standard biomedical terminologies, including SNOMED CT. Although the UMLS does not currently integrate HPO, it is expected to provide a reasonable coverage of phenotypes through its source vocabularies. In the UMLS Metathesaurus, synonymous terms from various sources are assigned the same concept unique identifier, creating a mapping among these source vocabularies. Terminology services provided by the UMLS support the lexical mapping of terms to UMLS concepts. Additionally, each UMLS concept is assigned one of the 15 Semantic Groups, which represent broad domains, including Disorders, Anatomy and Physiology. The 2013AB version of the UMLS is used in this work.

Related work

Researchers have investigated the representation of phenotypes through pre- and post-coordinated terms. Groza et al. developed an automated approach for decomposing skeletal phenotype concepts defined in HPO [9]. Oellrich et al. proposed an automated transformation of pre-coordinated phenotypes into Entity-Quality (EQ) statements for achieving interoperability between phenotype ontologies and compare their results to manually created EQ statements available for about half of the terms in HPO [10].

Besides our previous study [4], there have been a few efforts to study the coverage of phenotypes in standard terminologies such as SNOMED CT. Sollie et al. found that there are sizable gaps in SNOMED CT for metabolic disorders (and possibly for other classes of rare and genetic disorders) [11]. However, when Beck et al. assessed the suitability of HPO, ICD10, MeSH, SNOMED CT, and the Human Disease Ontology (DO) for describing GWAS traits, they concluded that, despite generally poor coverage (~20%), partial term matching to SNOMED CT is most successful [12].

These findings suggest, that there is a need for systematic improvement of the coverage of phenotypes in SNOMED CT, and that such an effort might benefit from decomposition techniques similar to prior work [9,10].

Specific contribution

The specific contribution of this work is to identify templates in SNOMED CT for the creation of post-coordinated expressions for phenotype concepts from HPO. This approach significantly extends the mapping to pre-coordinated concepts used in most mapping studies, including our earlier work on the coverage of HPO terms in SNOMED CT.

Methods

Our approach to assessing the coverage of HPO phenotypes in SNOMED CT can be summarized as follows. Starting from HPO terms with no lexical mapping to pre-coordinated SNOMED CT, we identify frequent modifiers and transformation rules in order to make HPO terms compatible with SNOMED CT. We examine the logical definition of existing phenotype concepts in SNOMED CT for templates. We then apply the transformation rules in order to decompose the HPO terms into simple elements. Finally, we combine them again into post-coordinated expressions consistent with the templates.

Establishing a list of modifiers and transformation rules for HPO terms

Starting from HPO terms with no lexical mapping to pre-coordinated SNOMED CT through the UMLS, we analyze word frequencies in order to identify frequent modifiers. More specifically, one author (FD) manually reviewed samples of terms containing words occurring more than 25 times in HPO terms (150 words). Frequent words include “abnormality [of]” (1126), “aplasia/hypoplasia” (134) and “congenital” (44). In addition, we noted frequent abbreviations for ordinals (e.g., “2nd”), while SNOMED CT typically uses the extended form (“second”).

We create four types of lexical transformations for making HPO terms compatible with SNOMED CT. These transformations are presented in increasing order of aggressiveness.

Level 1: Replace

We simply replace the abbreviations for ordinals by their expanded form. For example, the HPO term “Aplasia of the phalanges of the 4th toe” is transformed into “Aplasia of the phalanges of the fourth toe”.

Level 2: Split

HPO uses “/” for coordinating variants (e.g., “aplasia/hypoplasia”), while SNOMED CT does not. Here, we interpret “/” as disjunction, i.e., “aplasia or hypoplasia”. Therefore, we split expressions with words concatenated by “/” into two individual words, which we substitute to the corresponding expression in the term. For example, we transform the term “aplasia/hypoplasia of the thymus” into two terms, “aplasia of the thymus” and “hypoplasia of the thymus”, which both map to SNOMED CT.

Level 3: Demodification to disorder (D0)

HPO contains modifiers that specialize disorders (e.g., “congenital” specializes “bilateral cataract” to form “bilateral congenital cataract”). By removing these modifiers, we create a more general concept, which is more likely to map to SNOMED CT. For example, “bilateral cataract” maps to SNOMED CT.

Level 4: Demodification to anatomy, physiology or chemical substance (D1)

Another category of modifiers are those that denote a disorder (e.g., an abnormality) of a specific anatomical structure, physiological process or chemical substance. Examples of such terms include “Abnormality of the lip”, “Abnormality of intracranial pressure” and “Abnormality of prothrombin”. By removing “abnormality [of the]”, we extract the anatomical structure (e.g., lip), physiologic process (e.g., intracranial pressure) or chemical substance (e.g., prothrombin), which is the object of the abnormality.

Identifying templates for phenotype concepts

As shown in the example presented in the introduction, some pre-coordinated SNOMED CT concepts include the very modifiers (or constructs) we have identified as generally preventing the mapping to SNOMED CT. For example, the SNOMED CT concept “Congenital hypoplasia of kidney” contains “Hypoplasia”, which we have identified as a modifier (at the ***D1*** level). Such SNOMED CT concepts therefore suggest valuable templates for the decomposition of similar concepts. For example, the logical definition of the concept “Congenital hypoplasia of kidney” in SNOMED CT suggests a template for the modifier “Hypoplasia”.

***'Disease (disorder)'** and ('Role group (attribute)' some (('Associated morphology (attribute)' some **'Hypoplasia (morphologic abnormality)'**) and ('Occurrence (attribute)' some 'Congenital (qualifier value)') and ('Finding site (attribute)' some **'Kidney structure (body structure)'**)))*

The template suggested by this SNOMED CT concept is “Congenital hypoplasia of <ANATOMICAL STRUCTURE>” and corresponds to the following definition:

***'Disease (disorder)'** and ('Role group (attribute)' some (('Associated morphology (attribute)' some **'Hypoplasia (morphologic abnormality)'**) and ('Occurrence (attribute)' some 'Congenital (qualifier value)') and ('Finding site (attribute)' some **'<ANATOMICAL STRUCTURE> '**)))*

where <ANATOMICAL STRUCTURE> is what remains from the original term after demodification.

Applying transformation rules to HPO terms

We apply the transformation rules to HPO terms in increasing order of aggressiveness, from level 1 to level 4. Moreover, at a given level, the transformation rule is applied to not only the original terms, but also to the terms produced by all previously applied rules (at lower levels).

In practice, as shown in Figure 1, we first apply the ***Replace*** rule to the original terms (brown path). We then apply the ***Split*** rule to the original terms and to the terms produced by the ***Replace*** rule (green paths). The ***D0*** rule is applied to the original terms and to the terms produced by the ***Replace*** and ***Split*** rules (blue paths). Finally, we apply the ***D1*** rule to all the terms (pink paths).

For example, starting from the original term "Congenital adrenal gland hypoplasia", the rules ***Replace*** and ***Split*** do not produce any results. The modifier "Congenital" is removed by rule ***D0***, producing the demodified disorder term "adrenal gland hypoplasia". Finally, the modifier "hypoplasia" is removed by rule ***D1***, producing the term "adrenal gland", which corresponds to an anatomical structure.

Mapping demodified HPO terms to SNOMED CT concepts

Having removed the modifiers according to the transformation rules, we map all transformed terms to SNOMED CT through the UMLS using simple lexical mapping techniques [4]. More specifically, we attempt an exact match, followed by a normalized match using the functions provided by the UMLS Terminology Services API.

It is important to note that the first three rules (***Replace***, ***Split*** and ***D0***) are expected to produce more general terms for disorders, and yield mappings to disorder concepts in SNOMED CT (light blue links on Figure 1). In contrast, the ***D1*** rule produces terms for anatomical structures, physiologic processes or chemical substances. These terms are expected to map to entities of these types in SNOMED CT (orange link on Figure 1). For example, the term "factor XIII" (demodified from the HPO concept "Reduced factor XIII activity" [HPO:HP_0008357]) is mapped to the SNOMED CT concept "Factor XIII" [SNCTID: 319930009].

Of note, the original term and several demodified terms that derive from it may map to SNOMED CT. For example, "Congenital adrenal gland hypoplasia" (original HPO term), "adrenal gland hypoplasia" (produced by ***D0***) and "adrenal gland" (produced by ***D1***) all map to SNOMED CT. In this case, precedence is given to the mapping from the original term or to the mapping derived from the less aggressive transformation.

Creating post-coordinated expressions for HPO terms

In this preliminary work, we focus on expressions for D1 level modifiers, because D1 transformation rules tend to be more productive compared to D0 rules.

Using the templates suggested by existing SNOMED CT concepts, we generate post-coordinated expressions by inserting into the template the anatomical structure, physiologic process or chemical substance extracted by the transformation rule ***D1***. (An occasional D0 modifier may also have been removed from the term, but the final mapping happens at level D1.)

For example, the term "Macular" is extracted from the original HPO term "Macular hypoplasia" [HPO:HP_0001104] by the ***D1*** rule. It is mapped to the SNOMED CT concept "Macula lutea structure (body structure)" [SNCTID:362517001]. The modifier "hypoplasia" is associated with the template "Congenital hypoplasia of <ANATOMICAL STRUCTURE>", into which we insert the anatomical structure concept "Macula lutea structure (body structure)". The resulting logical definition for "Macular hypoplasia" is as follows.

'Disease (disorder)' *and ('Role group (attribute)' some (('Associated morphology (attribute)' some* ***'Hypoplasia (morphologic abnormality)'****) and ('Occurrence (attribute)' some 'Congenital (qualifier value)') and ('Finding site (attribute)' some* ***Macula lutea structure (body structure)'****)))*

Table 1 – List and count of modifiers organized in 4 levels: R (REPLACE), S (SPLIT), D0 and D1.

Description	n
Level R: Modifiers preventing terms from being mapped to disorders Modifiers for substitution patterns (one-to-one) *1st => first, 2nd => second, 3rd => third, 4th => fourth, 5th => fifth*	5 (present in 1,193 HPO terms)
Level S: Modifiers preventing terms from being mapped to disorders Modifiers for substitution patterns (one-to-two) Terms containing a "/" are split into two terms, for example: *Aplasia/Hypoplasia of kidney => Aplasia of kidney; Hypoplasia of kidney*	69 (present in 543 HPO terms)
Level D0: Modifiers preventing terms from being mapped to disorders *asymmetric, asymmetrical, bilateral, complete, congenital, cutaneous, generalized, lethal, marked, mildly, multiple, nearly, osseous, partial, patchy, severely, symmetric, symmetrical, unilateral, Alcohol-induced, Aminoglycoside-induced, Anesthetic-induced, Aspirin-induced, Cold-induced, Drug-induced, Effort-induced, Exercise-induced, Fava bean-induced, Heparin-induced, Radiation-induced, Stress-induced, infection-induced, Viral infection-induced, Warfarin-induced, ", recurrent", ", acute", ", chronic"*	37 (present in 1,129 HPO terms)
Level D1: Modifiers preventing terms from being mapped to anatomical structures/physiological processes/chemical substances *abnormal, abnormality, absence, absent, activity, agenesis, aplasia, aplastic, atresia[s], atrophy, bracket, broad, bullet shaped, bullet-shaped, chevron shaped, chevron-shaped, cone shaped, cone-shaped, contractures, curved, decreased, deficiency, degeneration, delayed, duplication, dystrophy, eeg, elevated, enlarged, fragmentation, hypoplasia, hypoplasic, hypoplastic, impaired, increased, irregular, ivory, loss, lytic defect[s], malrotation, number[s], osteolytic defect[s], prominent, pseudoepiphysis, reduced, rhomboid shaped, rhomboid-shaped, rudimentary, sclerosis, shortened, shortening, small, sparse, stippling, symphalangism, synostosis, thin, triangular, triangular shaped, triangular-shaped, wedge shaped, wedge-shaped, widened, widening*	65 (present in 8,864 HPO terms)

Results

Establishing a list of modifiers and transformation rules for HPO terms

As mentioned earlier, we identified four transformation rules (***Replace***, ***Split***, ***D0*** and ***D1***). As shown in Table 1, each rule is associated with a list of substitution patterns for replacement (***Replace***, ***Split***) or modifiers to be removed (***D0***, ***D1***). The number of patterns/modifiers per transformation rule ranges from 5 (***Replace***) to 69 (***Split***). The most frequent modifiers in HPO terms are those from the ***D1*** list (65 modifiers found in 8,864 HPO terms).

Identifying templates for phenotype concepts

As shown in Table 2, we identified 12 templates corresponding to modifiers at the ***D1*** level (with an occasional ***D0*** modifier), corresponding to five distinct logical definitions. Each template has the form:

{$modifier_1$, $modifier_2$, …, $modifier_n$} <ENTITY TYPE>

(e.g., {absence of}<ANATOMICAL STRUCTURE>)

Or : <ENTITY TYPE>{$modifier_1$, $modifier_2$, …, $modifier_n$}

(e.g., <ANATOMICAL STRUCTURE>{absent})

Each template is associated with a logical definition. Multiple templates can share the same logical definition. For example, the two templates listed above have the same logical definition. One of the authors (JTC) familiar with the SNOMED CT concept model inspected the templates for validity.

Applying transformation rules to HPO terms

The results of the successive application of transformation rules to HPO terms are depicted in Figure 1. The number of terms generated by each rule is listed next to the corresponding arrow. For example, 1,057 terms result from transformation ***D1*** applied to the 1,193 unique terms resulting from the ***Replace*** transformation (pink path ***R→D1***).

Mapping demodified HPO terms to SNOMED CT concepts

As we showed in our previous work [4], the mapping of the 16,413 original HPO terms to SNOMED CT through UMLS results in 3,081 HPO classes mapped to 4,215 SNOMED CT disorder concepts. Additionally, a total of 2,865 modified HPO terms (2,109 unique HPO classes) results from the three transformation processes (***Replace***, ***Split***, ***D0***). These disorder terms map to 515 SNOMED CT classes. The ***Replace*** transformation does not yield any new mappings. The ***Split*** transformation yields 55 mappings, of which 47 are new (i.e., not produced earlier). Transformation ***D1*** yields 2,857 mappings to anatomical structure, physiologic process or chemical substance concepts in SNOMED CT, 2,099 of which are new. The details of the mapping results can be found in Figure 1. Note that these mappings to pre-coordinated concepts in SNOMED CT only contribute to the post-coordination strategy developed in this paper.

Creating post-coordinated expressions for HPO terms

In this proof-of-concept investigation, we identified 12 templates involving 10 ***D1*** modifiers (and 3 additional ***D0*** modifiers removed when necessary). The instantiation of the logical definitions associated with these templates covers 1,617 HPO classes. Compared to the 3,081 mappings to pre-coordinated SNOMED CT concepts, this approach increases the coverage of HPO classes in SNOMED CT by roughly 50% through post-coordination.

Discussion

Our approach is very productive, yielding substantial gain in terms of number of mappings. More specifically, we developed post-coordinated expressions for 1,617 HPO classes that were not previously mapped to SNOMED CT classes, increasing the total number HPO classes mapped to SNOMED CT by 50%.

A high level of implicit knowledge was observed in HPO. For example, the notion of congenitality is usually assumed, rather than stated in HPO terms. While understandable in the context of clinical genetic phenotypes, it hinders the mapping to other terminologies. In contrast, SNOMED CT uses the qualifier value "congenital" to explicitly denote congenitality. Moreover, the finer-grained definitions supported by post-coordination make it possible to represent laterality (unilateral, bilateral, left, right), which is generally not represented in pre-coordinated terminologies.

Some of the templates we created do not fit the SNOMED CT concept model (e.g., {EEG with} <PHYSIOLOGICAL PROCESS> for electroencephalogram waveforms description) or lack specific pre-coordinated classes (e.g., for specific enzymes {decreased activity of} <CHEMICAL SUBSTANCE>). Additional work is needed to explore how these templates could be represented in SNOMED CT.

In future work, we want to identify templates for ***D0*** modifiers. We also want to assess the logical validity of the post-coordinated expressions we created by classifying them with the description logics classifier used by SNOMED CT. Finally, we would like to test the applicability of this method for mapping other specialized terminologies to SNOMED CT.

Conclusion

In this preliminary study, we explored the automatic mapping of HPO terms to SNOMED CT through post-coordination. Through this novel approach, we were able to increase the current number of mappings by 50%.

Abstract

Objective: This work presents a Modeling Language and its technological infrastructure to customize the vocabulary of Communication Boards (CB), which are important tools to provide more humanization of health care.

Method: Using a technological infrastructure based on Model-Driven Development (MDD) approach, our Modeling Language (ML) creates an abstraction layer between users (e.g., health professionals such as an audiologist or speech therapist) and application code. Moreover, the use of a metamodel enables a syntactic corrector for preventing creation of wrong models.

Results: Our ML and metamodel enable more autonomy for health professionals in creating customized CB because it abstracts complexities and permits them to deal only with the domain concepts (e.g., vocabulary and patient needs). Additionally, our infrastructure provides a configuration file that can be used to share and reuse models. This way, the vocabulary modeling effort will decrease over time since people share vocabulary models.

Conclusion: Our study provides an infrastructure that aims to abstract the complexity of CB vocabulary customization, giving more autonomy to health professionals when they need customizing, sharing and reusing vocabularies for CB.

Model-Driven Development; Modeling Language; Metamodel, eHealth, Assistive Technology; Communication Board; Speech Impairment.

Introduction

People have speech problems for many reasons (e.g., autism, neck injury, ASL, cerebral palsy, stroke, dysarthria, and tracheostomy) and they communicate their needs, desires and complaints in an alternate way. The absence of this communication causes lack of thinking, frustration, anger, and social exclusion of these individuals [1,2]. According to Palerm & Ruiz [3], until six years old, children have their cognitive development directly related to language development. The lack of communication with other people, in this stage of life, can irreversibly damage their intellectual capacity.

In this context, Augmentative and Alternative Communication (AAC) [4] is a field of Assistive Technology [5] dedicated to expanding the communication skills of these people. According to the American Speech-Language-Hearing Association (ASHA) [4], AAC is the area of clinical practice that attempts to compensate for difficulties or disabilities demonstrated (either temporarily or permanently) by individuals with severe communicative disorders. AAC resources recognize and value all communication attempts of an individual – whether through gestures, facial expression, eye gaze, writing or drawings – and try to complement them.

In the AAC context, Communication Board (CB) (Figure 1) is one of the best ways to address basic needs of expression, because the CB is a set of symbols and captions that represent objects, actions, feelings, etc. Therefore, the communication is established using a selection of symbols and captions that express what the user wants to say. Generally, they are arranged into groups and colors in order to facilitate symbol location tasks. The most used pattern is the Fitzgerald Key [6] notation, where the vocabulary is divided into six colored groups as follows: 1) Nouns in orange; 2) Pronouns in yellow; 3) Verbs in green; 4) Adjectives in blue; 5) Social Expressions in pink; and 6) Miscellany in white.

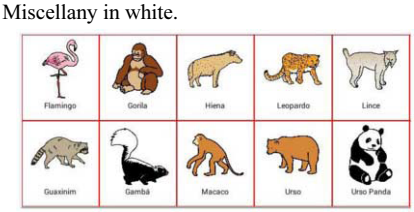

Figure 1 – Communication Board example

The universe of eHealth technologies to facilitate communication is increasing and can now help several speech-impaired people to communicate and socialize with others. According to the theory of communication [7], effective communication can only occur between people (i.e., sender and receiver) who understand the code (i.e., vocabulary) and can code (sender) and decode (receiver) the message. This way, the vocabulary is a key concept in communication, and it is unique for each person.

Despite all eHealth potential benefits of CB, most of the solutions do not allow vocabulary customization for a given patient. Most of them come with a huge set of default symbols which is more than necessary for effective communication, and causes cognitive overload in the user (e.g., many options to choose from in the search area). The CB eHealth solutions that allow vocabulary customization do so by filling out fields in a Graphical User Interface (GUI) [4, 5]. This approach has some problems, for example, since each element is separately built, it is not possible to create a cohesive relationship among them. Thus, in this scenario, a patient using a CB can make all possible combinations with CB vocabulary elements, some of them causing communication cohesion problems. For instance, it is possible for communicating something like *"I want to wear an apple"*. This information is not consistent. The verb *"wear"* needs an outfit as a complement, and the noun *"apple"*, a verb related to food. Moreover, the vocabu-

lary customization made from the fulfillment of fields in a GUI makes the job of users harder (e.g., audiologist or speech therapist) because there is no global overview of the created content. This way, the user can mistakenly insert the same word more than once, for example.

In order to propose a better eHealth solution for CB vocabulary customization and design a viable technology for this task, it is worth thinking about some questions: Is there a way to express our vocabulary organization mental model and discuss it with another person? What methods are there to abstract the complexity of this process? There is a domain-specific solution? How can eHealth improve this process? Is there a standard for CB vocabulary customization? How can developers adopt reusability of the vocabulary? Can productivity be enhanced? What about interoperability?

After thinking about those questions and aiming to overcome the previous shortcomings (i.e., cognitive overload, no cohesion relationship and no global vision), we have developed a new approach, based on Model-Driven Development (MDD) [10], visual Modeling Language (ML) [11] and metamodel [12] in order to customize CB vocabulary. Many successful solutions for eHealth [9, 10] use MDD. This choice can be explained by the main characteristic of MDD, the creation of an abstraction layer to deal with complexity. Moreover, we can process visual information efficiently, about a quarter of our brain is devoted to vision, more than all our other senses combined [15]. Information represented visually is also more likely to be remembered due to the picture superiority effect [16]. As a consequence, our proposal tends to be more intuitive and easy, giving autonomy to health professionals in performing these tasks.

In this context, the main objective of this paper is to present how Software Engineering, more specifically Model-Driven Development (MDD) based on Modeling Language (ML) and metamodel, can be used to improve communication and quality of software programming for Augmentative and Alternative Communication (AAC). Additionally, we discuss how these technologies can improve health humanization.

Materials and Methods

Model-Driven Development

Model-Driven Development (MDD) is defined as a software development paradigm which uses models as the key artifacts in all development phases. For instance, a Modeling Language (ML) is a visual notation and it is defined by an abstract syntax (i.e., grammar), a concrete syntax (i.e., representation or notational elements), mappings between abstract and concrete syntax, and a description of the semantics [12].

In MDD, models are more than documentation items, they are executable objects [12]. In other words, once the models are created, target code can be generated and then compiled or interpreted for execution. Thus, MDD and ML hide implementation details, which speeds up the software development process by reducing its complexity [12]. Moreover, visual notations tend to provide higher-level abstraction than textual ones, because it is domain-specific. In this way, ML tends to be easier than pure coding, especially because the ML visual notation aims to deal only with the domain concepts and abstract textual representation, hiding implementation details.

MLs are supported by Computer-Aided Software Engineering (CASE) tools that can detect errors earlier, or even prevent them from happening, guide towards preferable design patterns, check completeness by informing about missing elements, reduce modeling work by applying conventions and default values, support full code generation, and keep specifications consistent [12].

The specification of a ML in MDD is based on the metamodel concept [12], which provides an abstract syntax to distinguish valid and invalid models. That is, a metamodel (or abstract syntax) of a ML describes concepts, relationships between them, and structuring rules that constrain the combination of these concepts according to the domain rules of a ML. Thus, a metamodel presents a precise specification of modeling concepts and well-formed rules needed for creating syntactically correct models. Consequently, a metamodel is as useful for a ML as grammar is for a programming language.

In this context, it is important to highlight that a metamodel for ML offers the basic definitions (i.e., metadata) to develop CASE tools, which can be done using free (e.g., Eclipse Modeling Project [17]) or proprietary (e.g., Microsoft Modeling SDK for Visual Studio [18]) technologies.

Our Proposal

Figure 2 illustrates an overview of our eHealth proposal for CB vocabulary customization using MDD. The proposal consists of two components: 1) A CASE Tool for modeling the CB vocabulary; and 2) The CB Generator for generating an application (*app*) for a touch screen device.

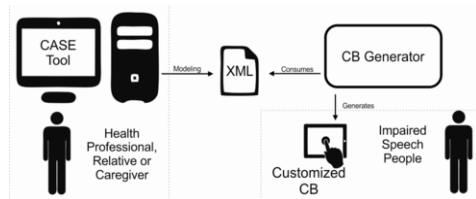

Figure 2 – Our proposal overview

This paper focuses on the use of the MDD paradigm for building an infrastructure that allows health professionals (e.g., audiologist or speech therapist) to easily customize CB vocabulary for each patient.

In order to build this infrastructure, we need to define our application domain, that is the CB vocabulary universe. Following this, we need to define the ML (i.e., concrete syntax and abstract syntax) for this domain. Our ML, named Communication Board Modeling Language (CBML), is described in the following.

The concrete syntax (i.e., notational elements) was defined based on the original Fitzgerald Key notation [6]. Such notation was chosen because it is a widely used pattern for professionals (e.g., audiologist or speech therapist) in CB eHealth solutions. The abstract syntax (i.e., metamodel) is elaborated after the concrete syntax and defines the domain rules, that means, how to connect the notational elements to build correct models. Our ML was defined to allow vocabulary categorization and to limit constructions with cohesion problems. The CBML (i.e., notational elements and metamodel) will be further discussed in the Results section.

With these previous artifacts (i.e., notational elements and metamodel) the software (i.e., CASE Tool and CB Generator) can be implemented. The CASE Tool is based on a desktop computer and its users are health professionals, familiars or caregivers. In turn, the CB Generator is based on a mobile device with a touch screen (e.g., tablets and smartphones) and its users are people with oral communication impairments. These two modules communicate through a file in an Extensible Markup Language (XML) [19] format that is generated from the model designed in the CASE tool. This XML file contains all of the vocabulary modeled in the CASE tool and

serves as an input to the CB Generator to customize the CB. The CASE Tool was discussed in another paper [20] and a brief discussion of CB Generator is shown in the Results section.

It is important to mention that CB customization (e.g., contrast color, size and number of icons per screen) and its usability requirements (e.g., sonorous feedback and scanning mode) are the responsibility of the CB Generator. The ML only defines the CB vocabulary.

Results

CBML

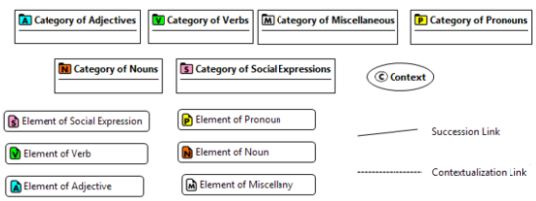

Figure 3 – CBML notational elements

Figure 3 shows the CBML elements, based on the original Fitzgerald Key notation [6]. In this work, the white color is also used to represent a *Context* concept. The notational elements of CBML are:

1. *Categories*, represented by a white rectangle with a folder pictogram with the initial letter of group name and color, as specified by the Fitzgerald Key pattern;
2. *Elements*, represented by a white rectangle with a file pictogram with the initial letter of group name and color, as specified by the Fitzgerald Key pattern;
3. *Context*, represented by a white ellipse with a circle pictogram with the letter *"C"*;
4. *Succession Link*, represented by a continuous line;
5. *Contextualization Link*, represented by a dashed line.

Regarding pictograms, a *Category* is represented by a folder icon that can contain other folders (subcategories) and several *Elements*, which are represented by file icon.

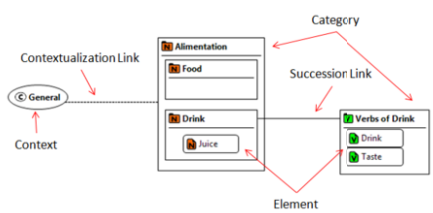

Figure 4 – CBML model example (node-link diagram)

Figure 4 demonstrates how CBML notational elements can be organized. In this example, the concept *"Alimentation"* was categorized into *"Food"* and *"Drink"*, and the subcategory *"Drink"* has the *Element "Juice"*. The *Category "Verbs of Drink"* has the *Elements "Drink"* and *"Taste"*, and it is connected to the *"Drink" Category* through a *Succession Link*. The *"General" Context* is connected to *"Alimentation"* through a *Contextualization Link*. Due to the *Succession Link*, a semantic relationship is created between words. This way, the user cannot build sentences with cohesion problems (e.g., *"drink a food"*), because the verb *"Drink"* is connected only to the *"Drink" Category*.

Metamodel CBMM

The Communication Board MetaModel (CBMM) is designed considering that the CB vocabulary model is essentially a node-link diagram [21], where a CB vocabulary diagram is composed of nodes representing *Categories*, *Elements* and *Contexts*, and links representing *Succession Links* and *Contextualization Links*. In Figure 4 there are some nodes and links of the CB vocabulary model. A conceptual view of our metamodel is presented in Figure 5.

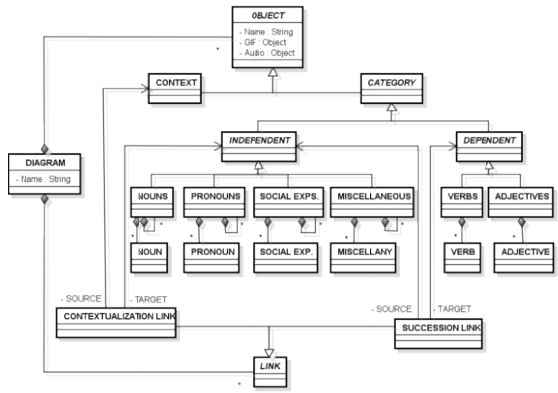

Figure 5 – The CBMM metamodel

In CBMM there are three main meta-concepts: *Diagram*, *Object* and *Link*. *Diagram* is the root meta-concept that corresponds to the drawing area of a CB diagram. For this reason, *Diagram* can have many instances of *Object* and many instances of *Link*, which cannot exist without a *Diagram*. An *Object* corresponds to an icon in the CB GUI and it is characterized by a caption, an image, and an audio, which are represented by *Name*, *GIF* and *Audio* attributes. Alongside these main meta-concepts, our metamodel has two specialized meta-concepts of *Object*, *Category* and *Context*, which are described as follows.

The *Category* meta-concept is responsible to group concepts according to the Fitzgerald Key notation, and it is specialized in two meta-concepts, *Dependent* and *Independent*, which are presented as follows.

On one hand, the *Dependent* meta-concept is responsible for organizing those concepts of the Fitzgerald Key that can generate cohesion problems (e.g., *"eat a juice"* and *"soft milk"*). It is specialized into two meta-concepts, *Verbs* and *Adjectives*. On the other hand, the *Independent* meta-concept is responsible for organizing the other concepts and it is specialized in four meta-concepts: *Nouns*, *Pronouns*, *Social Expressions* and *Miscellaneous*. Note that each meta-concept of the Fitzgerald Key notation is referenced in plural form (e.g., *Nouns*, *Pronouns*) and they are associated with the notational element of *Category* (Figure 3). These meta-concepts, in plural form, can be recursively composed to create a subcategory in a *Category* (except *Verbs* and *Adjectives*). Additionally, each meta-concept in its plural form is composed of many instances of another meta-concept, in singular form, that is associated with the notational element of an *Element* (Figure 3).

The *Context* meta-concept, specialized from the *Object* meta-concept, is related to the environment concept (e.g., *"bed"* in a *"domestic context"* and *"stretcher"* in a *"hospital context"*).

In sequence, the *Link* meta-concept is specialized into *Contextualization Link* and *Succession Link*. In the first case, the *Contextualization Link* is responsible to connect a *Category* of concepts to a *Context*. In this way, the *Contextualization Link*

has a *source* relationship with a *Context* and a *target* relationship with an *Independent Category*. In the second case, the *Succession Link* is responsible to avoid communication cohesion problems. In this way, the *Succession Link* has a *source* relationship with an *Independent Category* and a *target* relationship with a *Dependent Category*.

CASE Tool and Front-end Application

In order to demonstrate the feasibility, expressiveness, and usefulness of our ML and metamodel, we have developed the Communication Board CASE (CBCASE), that was discussed in another paper [20]. The front-end application is in development and we already have a low-fidelity prototype (Figure 6).

Figure 6 – Front-end interface (low-fidelity prototype)

The main idea is the use of a grid format in landscape mode with a toolbar at the bottom. The main objective of the grid format is to facilitate use by people with motor impairment through the use of Assistive Technologies as scanning mode and binary switches [22]. This allows people to use our CB without the need to touch it. For instance, the end user can easily access the main functions and options such as navigation, fast answers, and favorite expressions right from the toolbar.

Discussion

Communication, in its various forms, is a basic human need for people to socialize, express ideas, feelings and desires. The absence of this necessity causes frustration, anger and social exclusion of these individuals. A study with patients who received mechanical ventilation during their period in an intensive care unit noted that the level of frustration in trying to communicate decreased with the insertion of a CB [1]. We know emotions influence the physical and psychological health of the patient. In this case, it was observed they were calmer when they could effectively communicate their complaints, sensations and feelings.

In this context, our study aims to address three main objectives: 1) achieve health humanization by enabling dialogs between health professionals and patients; 2) provide an environment to allow health professionals (e.g., audiologist or speech therapist) to easily customize, share, discuss and reuse CB vocabulary; and 3) offer a CB with customized vocabulary for each patient, giving voice, autonomy and quality of life to them.

Vocabulary is the communication core and depends on several factors (e.g., age, culture, location, and context) in such a way that it is customized for each person. The current eHealth solutions for CB, if they allow vocabulary customization, do this by filling out the fields in a GUI. This approach has some problems, for example, no global vision of created content and cohesion problems during use. This customization problem could be solved by using an ontology editor (e.g., Protegé). However it is a generic editor (i.e., it is not domain-specific) that is too complex to be used, even for computer professionals, thus making the modeling work a difficult task.

With the MDD paradigm it is possible to create an abstraction layer between the user who will create the CB vocabulary (e.g., health professional as audiologist or speech therapist) and the implementation code. Using ML the user only needs to know about the specific context (e.g., vocabulary and patient needs). This way, the user, who deeply knows about the patient environment and needs, can do it on their own without depending on programmers.

The CBML allows the CB vocabulary modeling in a diagrammatic way, meaning it can be done, for example, with a pencil on a piece of paper. This feature enables discussion among users to improve the vocabulary and, when it is done, the user can model it in the CASE tool for generating the application code. On the other hand, our architecture provides an infrastructure to encourage people to share vocabularies through XML files. This way, the effort for modeling a vocabulary will decrease with time as XML files are shared and reused. Moreover, these XML files can be used as a standard for CB vocabulary customization, enabling interoperability among different platforms.

Additionally, our solution (i.e., CBML, CBMM, CBCASE and the front-end application) prevents wrong models and cohesion problems because it is based on a metamodel. That is, a metamodel (or abstract syntax) of a ML describes the concepts, the relationships between them, and the structuring rules that constrain the combination of these concepts according to the domain rules of a ML. In other words, a metamodel is useful to provide a precise definition of all modeling concepts and well-formed rules needed for creating syntactically correct models [12]. In this context, we enumerate the main well-formed rules that are intrinsically assured by our metamodel (Figure 5). That is, these well-formed rules are directly derived from our metamodel and, for this reason, can be checked against it. These rules are:

1. An *Object* (e.g., *Category* and *Context*) cannot be connected to another *Object* without a *Link*, and vice-versa. That is, neither an *Object* can be directly connected to other *Objects* nor a *Link* can be directly connected to other *Links*;
2. A *Link* cannot be created without an *Object* as a source and another as a target. That is, a *Link* cannot be depicted isolated in the drawing area;
3. A *Subcategory* can only be built within another *Category* of the same type (e.g., nouns, pronouns, social expressions and miscellaneous);
4. An *Element* can only be instantiated within a *Category* of the same type (e.g., nouns, pronouns, social expression, miscellaneous, verbs and adjectives);
5. A *Succession Link* can only exist between *Dependent Categories* (e.g., verbs and adjectives) and *Independent Categories* (e.g., nouns, pronouns, social expressions and miscellaneous);
6. A *Contextualization Link* can only exist between *Context* and *Independent Categories* (e.g., nouns, pronouns, social expressions and miscellaneous).

Conclusion

Communication is an indispensable factor to address health humanization. Both aphasic patients and health professionals need to be heard, establishing a network of dialogs to lower distances, connecting people and increasing patient quality of

life. Current solutions, in allowing vocabulary customization, do it by filling out fields in a GUI. This approach causes problems such as cognitive overload, no cohesion relationship in message, and no global vision of the modeled content. Consequentially, it makes the job of health professional who will model the vocabulary harder, therefore generating a CB with low usability for the user.

In this paper, we presented the use of the MDD paradigm for eHealth, especially for CB, which aims to help people unable to use speech to communicate. In this context, MDD provides an abstraction layer to enable health professionals to easily customize a vocabulary for each patient.

We presented CBML, the ML to diagram and discussed the vocabulary, and CBMM, the metamodel that describes the concepts and how to combine them according to the domain rules. CBML and CBMM, together, provide a new paradigm for the CB vocabulary customization. Our proposal is original and provides a way to organize a vocabulary as our mental model. Another point to highlight in our solution is the possibility to create a new standard for CB vocabulary customization. It can be made through our configuration file, enabling interoperability among platforms. Furthermore, using the MDD approach, it is possible to work directly with domain concepts, thus facilitating learning and use.

To demonstrate the feasibility, expressiveness and usefulness of CBML and CBMM, we have developed the CBCASE that was discussed in another paper [20]. The main contribution of this paper is the MDD approach, using ML and metamodel, that can be used as a standard for CB vocabulary customization.

In conclusion, our work contributes to the advancement of the state of the art of MDD, ML and metamodel for CB; it provides a novel perspective of scientific research and industrial application in the field of vocabulary customization for a given patient. Furthermore, our metamodel is the first one that aims to customize a CB vocabulary. We highlight three main features of our ML that are guaranteed by our metamodel: 1) *Category*, to provide vocabulary modularization; 2) *Succession Link*, to avoid cohesion problems (e.g., *"wear an apple"*); and 3) *Contextualization Link*, to filter the vocabulary according to the situation (e.g., home, hospital, school).

Abstract

Over the last decade, interoperability of the Electronic Health Record (EHR) is becoming more of a reality. However, inconsistencies in documentation such as pain are considered a barrier to obtaining this goal. In order to be able to remedy this issue, it is necessary to validate reference models that have been created based upon requirements defined by Health Level 7 (HL7), Logical Names and Codes (LOINC) and the Intermountain Clinical Element Model using external published sources and guidelines. Using pain as an example of complex and inconsistent documentation, it was found that the reference model based upon these standards is valid because the data elements identified are broad and can meet the needs of each sub-domain within the primary domain of pain.

Keywords:

Pain documentation, clinical reference model.

Introduction

Converting a hospital system that has been using various electronic health records (EHR) to a single electronic medical record (EMR) can be a significant challenge. Variation in clinical workflows may serve as rationales to request modifications to the user interface (UI) of an EHR, including data terminology and definitions, for specific settings or specialty care areas. While a goal of these modifications may be to increase productivity by providing tailored screen interactions for end-users, the integrity and consistency of data capture across an organization suffers. The creation of a reference data model and validation based upon external published references is critical to steer consistent data capture in any organization. "Data standards, including terminologies and common data elements (CDE), is a critical first step towards achieving automated data integration."[1]

This study is focused on Partners HealthCare (Partners), a large integrated health care delivery system in the Northeast region of the United States that consists of 12 hospitals that have been affiliated or acquired over the last 20 years. Each hospital has different inpatient and outpatient EHR's, which are either internally developed or vendor provided. The Partners eCare (PeC) Program is an enterprise-wide effort to implement a single vendor-based EHR[9]. The opportunity to convert all the hospitals to one EHR platform has given way to the need to standardize documentation throughout all the specialties. As the United States and other countries increase their infrastructures and capabilities to share electronic healthcare data, consistent data definitions based on clinical reference models will be critical.[2] If clinical data is inconsistently defined and captured, an important goal is to iteratively identify and resolve these data inconsistencies, starting while the new EHR platform is being configured, but continuing throughout the system deployment phases. Ideally, this iterative process should start with high priority clinical documentation topics.

Complexity of Pain Documentation

Pain documentation is an example of an important and complex clinical documentation topic. The complexity of pain documentation is derived from its broad application to a variety of clinical settings, specialty specific requirements, and multiple pain subtopics, such as cancer-related pain or acute post-procedural pain related to a joint replacement. The management of pain requires complex care coordination, clinical decision-making, and trending and evolution of the patient's response to treatment[3]. As complexity of care delivery increased, so does the complexity of documentation to reflect that care. Even educated, experienced medical professionals may rely on past personal experiences, outdated teachings, and be more resistant to incorporating new practice pain management guidelines which can directly affect the degree of documentation completed.[4] Therefore, consistency in application of evidenced-based pain management practice is the primary means to combat under treatment of pain.[5] Standardizing the complexities of structured data capture for pain documentation is hypothesized to increase continuity of care, improve the integrity and efficiency of secondary data use, and ultimately improve patient care. The first step is to review an existing reference model and validate it using external published sources.

At Partners, we have been identifying high priority clinical documentation topics, such as pain, to target for development of reference models. This work is performed as part of the PeC Program and includes ongoing collaborations between clinical experts, EHR analysts, and informaticians. Reference models are defined using a combination of sources, including Health Level 7 (HL7)[6], Intermountain's Clinical Element Model[7] and Logical Observation Identifiers Names and Codes (LOINC)[8]. However, implementing this reference model based on these requirements alone is not valid without the support of published external documentation. It is necessary to validate the model within each type of clinical setting and specialty specific requirements.

We describe in this paper the process we used to validate the reference model for pain, taking into account published evidence from a various sources.

Methods

Literature Review of Pain Documentation Guidelines

A literature search was performed in July of 2014 to retrieve publications related to pain documentation that were published before August of 2014. Multiple electronic databases such as Pub Med, Google Scholar, Google, and the Agency for Healthcare Research and Quality (AHRQ) National Guideline Clearinghouse (NCG) website was searched using the keywords "pain" and "documentation" or "chronic pain and documentation" or "acute pain and documentation" or "pain" and "guidelines" or "geriatric pain" or "pediatric pain". Our inclusion criteria were peer-reviewed publications related to acute or chronic pain documentation. We excluded articles that did not discuss discrete data elements related to pain documentation. In addition, articles that discussed pharmacological management of pain or specific interventions to decrease pain were also excluded. The initial search of the keyword "pain management" or "acute pain management" or "chronic pain management" yielded over 75,000 results. When the additional keyword of "documentation" was added, the results decreased to 455 results. After applying the exclusion criteria of pharmacological management or specific interventions, a total of 50 articles were identified. After reviewing the abstracts to determine if they met inclusion and exclusion criteria and removing overlapping articles, a total of 9 articles were selected for full-text review. After reviewing the content of several articles, it became evident that the Agency for Healthcare Research and Quality website needed to be searched. After searching the website using the keywords "pain guidelines", another 3 web pages within the National Guidelines Warehouse (NCG) powered by the AHRQ were identified. A total of 12 articles and web pages were identified to receive full review.

Categorization of literature and findings

Articles were then categorized into two areas of interest: (1) national and international guidelines on general documentation and treatment, and (2) documentation of pain in certain situations. (e.g. treatment of cancer pain.) After reviewing these articles, new categories were derived based upon the type of pain that was being documented. Pain can be divided in to two major sub-topics: "Acute Pain" and "Chronic Pain."

Define a Comprehensive Reference Model for Pain Documentation that includes Acute and Chronic Pain

After reviewing which data elements were required to be documented, a reference model was created. Then each element definition was compared against the existing reference model that had been derived from HL7, Intermountain and LOINC. The outcomes of each data element were placed into three categories (1) Valid (V), (2) Missing Required (MR), (3) Missing Not Required (MN). The criteria for the data elements that were missing and required were elements that were present in the reference model derived from published sources and not present in the existing reference model. Criteria for the elements that were considered missing but not required were elements that appeared in the existing reference model and not in the reference model derived from published sources. Validated elements were considered a 1:1 match or their definitions between each reference model were similar.

Results

Comprehensive Reference Model for Pain Documentation

Sub-categories of acute pain and chronic pain were assigned to specific situations if the guidelines stated that certain documentation was required. The sub-categories for acute pain were (1) self-reported pain perceptions following surgery, (2) geriatric pain management and (3) pediatric pain management. The sub categories for chronic pain were (1) malignant pain and non-malignant pain. Additional sub-types for non-malignant pain needed to be identified to which were (1) neuropathic pain, (2) musculoskeletal pain and (3) inflammatory pain.

Acute Pain

Acute pain has a set of data elements that make up its reference model. (Table 1). Acute pain consists of three sub-domains, (1)self-reported pain perceptions following surgery,

Table 2 – Self- Reported Pain Reference Model

Reference Model Elements[1]	Elements derived from published sources[1]	Validation Outcome[2]
Pain Onset	Pain History	*V*
Pain Onset (Hours ago)	Pain History	*V*
Speed of Pain Onset	Pain History	*V*
Pain Primary Location	Location	*V*
Pain Quality (Character)	Quality of Pain	*V*
Pain Periodicity	Frequency	*V*
Pain Temporal Pattern	M	*MN*
Pain Alleviating Factors	Alleviating Factors	*V*
Pain Aggravating Factors	Aggravating Factors	*V*

Pain Duration (Hours, Minutes)		*MN*
Associated Signs and Symptoms	Physiological and behavioral Responses to Pain	*V*
Patient Severity Score	Intensity of Pain	*V*
Pain Course	Pain Treatment	*V*
Relative Temporal Context	Quality of Life	*V*
M	Patient Education regarding pain management	*MR*

1 M= Missing
2 V= Validated, MN= Missing and Not Required, MR= Missing and Required

(2) geriatric pain management and (3) pediatric pain management.

These three sub-domains were chosen because of the specificity of how pain needs to be reported. The geriatric and pediatric pain populations were singled out due to the way the patients report and respond to pain stimuli. For example, cognitive status in geriatric pain management is significant because the self-reported pain may not be entirely accurate if the patient is confused. (Table 3). Self-reported pain (Table 2) also has its' specific requirements such as patient education regarding pain management while geriatric pain management required a cognitive status assessment as part of its documentation. Pediatric pain requires only Pain History, Pain Quality, Pain Pattern, Alleviating Factors, Aggravating Factors and Pain Intensity to be documented . In Self-reported perception of pain, it was found that the patient education regarding pain management is a required criteria to be documented. All other elements were considered to either be valid or missing but not required.

Table 3- Acute Pain: Geriatric Pain Management

Reference Model Elements[1]	Elements derived from published sources[1]	Validation Outcome[2]
Pain Onset	Present Pain	*V*

Chronic Pain

Chronic pain consists of two major sub-types: cancer-related pain and non-malignant pain (Table 4). Unlike acute pain, chronic pain sub-domains within the sub-types. Non-malignant pain is broken down in to 3 sub-types: Musculoskeletal and inflammatory pain, and neuropathic pain (Table 5). The minor differences between Data elements can be applied to chronic pain documentation using the Institute for Clinical Systems Improvement (ICSI) Assessment and Management of Chronic Pain Algorithm. [10] The reference models were found to be valid with no elements that were missing and required to be documented upon.

Discussion

Despite the fact that many of the data elements that are necessary for pain documentation are similar, the context of which they are being used can be different. A patient with acute pain is focused on how the pain began and how to resolve it. Using the definitions of the data elements within the sub-domains as a guideline that assist in resolving the problem because the documentation is very specific to each specialty and the sub-domains address the specifics in very broad terms with the understanding that they align to a specific data element within the current reference model. (e.g., Acute abdominal pain for GI specialty versus chronic back pain found in Orthopedics.) Validating each element in the reference model allows a one-to- many ratio to meet the needs in each situation.

Acute pain patients can convert to chronic pain after the initial injury has resolved. In this case, the patient would also convert over to the chronic pain sub-domain. The documentation would then qualify for a specific sub type and secondary sub-domain based upon the signs and symptoms. The implication for the reference model is that it can be used in different scenerios without having to be significantly changed. However, when considering the context of self-reported acute pain, it is necessary to understand the level of education the patient has regarding his or her pain management. In this case, it would be necessary to add the data element "Patient education regarding patient management" to this context in order to gain an accurate picture of the patient's pain and how it is being managed.

Chronic pain is focused on management of the pain overtime, as it may never resolve. By definition, chronic pain is pain persisting longer than three to six months, beyond the time that healing normally occurs.[11] Changes in the chronic pain pathways are usually permanent, may be present in the absence of an identifiable source, and have varying response to conventional analgesic medications.[5]

Table 4- Chronic Pain: Malignant and Non-Malignant

Reference Model Elements[1]	Elements derived from published sources[1]	Validation Outcome[2]

The definition of these data elements is one step in the process of configuring clinical documentation content in an EHR. The configuring of how the data elements are represented on a form is a separate and significant and complex process requiring information about the technical capabilites of the system and end-user requirements.

Limitations

The definitions were derived from national guidelines which could be in the process of being updated and thus making these definitions out of date at some point in the future. However, timely integration of the most up to date literature is a continuous struggle for all evidence-based practice and documentation. The search parameters were using keyword searches which, if not using the correct keyword, could have left a result out that may have made a significant contribution to the meaning of the definitions.

Conclusion

Validating a reference model using documentation derived from published sources is only a first step in creating standardized documentation across the entire healthcare system. The method of using evidence to validate reference models for specific clinical topics will be applied to other areas such as wound care, line placement, and living situation. Optimization of clinical data definitions within an EHR necessitates the assessment of broad clinical topics and validation of reference models for each topic that can be applied across settings and specialties in order to create consistent data output.

Consumer Health Information Needs and Question Classification: Analysis of Hypertension Related Questions Asked by Consumers on a Chinese Health Website

Haihong Guo[a], Jiao Li[a], Tao Dai[a]

[a] *Institute of Medical Information & Library, Chinese Academy of Medical Sciences, Beijing, China*

Abstract

This study built up a classification schema of consumer health questions which consisted of 48 quaternary categories and 35 annotation rules. Using such a schema, we manually classified 2,000 questions randomly selected from nearly 100 thousand hypertension-related messages posted by consumers on a Chinese health website to analyze the information needs of health consumers. The results showed questions in the categories of treatment, diagnosis, healthy lifestyle, management, epidemiology, and health provider choosing were 48.1%, 23.8%, 11.9%, 5.2%, 9.0%, and 1.9% respectively. The comparison of the questions asked by consumers and physicians showed that their health information needs were significantly different (P<0.0001).

Keywords:
Health Consumers; Information Needs; Hypertension; Question Classification; Consumer Health Informatics.

Introduction

The Internet is increasingly becoming a main resource for consumers to acquire health information. 80% of internet users (i.e. 59% of all adults) in the U.S. have looked online for health information [1]. In China, health channels of main portals and professional health websites have become one of the main resources for health consumers [2], and the number of internet users has increased to about 632 million in 2014 [3]. Many researches have proven that health related information online could impact consumers' health decisions and behaviors [1,4]. Health websites that target specific information needs are burgeoning in response to the high demand and impact [5]. However, making health information available does not necessarily guarantee its accessibility and usability [6]. Consumers have difficulty in expressing their information needs using accurate medical query terms, and further failed to retrieve relevant health information [78]. Thus, it is crucial to develop a method to identify health information needs from questions asked by consumers.

In previous studies, a series of templates were developed to guide question composition, and identify meaningful concepts and their relationships, which were further used to construct query strategy [9]. This method requires consumers to follow the scheme when asking questions, which would affect its usability. Some studies used metathesaurus (such as UMLS and the on-going Consumer Health Vocabulary) [10] to assign multi topics of questions so as to construct navigational exploration interface or generate semantic query strategy [11]. It is hard to specify the information needs (concerned aspect), although the topic has been identified. For example, though it could identify that a question was about hypertension, it was difficult to distinguish whether the user wanted to know its diagnosis, treatment, prognosis, or diet, for eaxmple. A promising way to overcome the shortage is to build up a question classification schema to define question topic and its concerned aspects [12].

For professional health-related questions, several classification schemas have been developed, such as the International Classification of Primary Care [13] and the Taxonomies of Generic Clinical Questions (TGCQ) [14,15]. They have proven to be useful when analyzing physicians' and case managers' information needs [15,16] but not suitable for consumers' questions due to the diffference of information needs between physicians and consumers [17,18]. A Layered Model of Context for Consumer Health Information Searching (LMCC) intended to describe consumers' interest topics on cognitive layers [19] but not define the classficassion schema in a systematic manner. In this study, we aim to build up a consumer health question classification schema to understand and specify users' informational needs.

To test the usefulness of classification schema, we used hypertension related questions asked by Chinese consumers as a test dataset. Hypertension has become the main risk factor of over half of cardiovascular diseases, such as stroke and coronary heart disease. There were 270 million patients (that is, at least 2 patients out of 10 alduts) with hypertension in China in 2012, and the number has continued to increase at a rate of 3.1% per year [20]. Thus, hypertension-related questions have become more frequently asked with large variability on the Internet.

Materials and Methods

Data Collection

Messages posted by health consumers from 01 January to 10 August 2014 with a tag of "hypertension (高血压)" or "blood pressure (血压)" under the Q&A (有问必答) section on xywy.com (http://www. xywy.com/, a Chinese health website with over 35 million users) were collected and imported into a MySQL database. The resulting database included 98,032 messages. To conduct an in-depth analysis of the questions contained in the messages, we randomly selected 2,000 messages.

"Question" is defined as a request that a consumer posted to the website on a certain subject to seek answers from professionals, which was identified based on meaning, not form. This study was focused on questions related to

hypertension (高血压), which was sometimes expressed as "high blood pressure (高血压)," or simply as "high pressure (高压)." So, we manually discarded messages that did not match the definition and that were irrelevant to hypertension, but with the similar words such as "high pressure oxygen (高压氧)," "hyperbaric cabin (高压舱)," "high voltage(高压电)," "pressure cooker (高压锅)," etc.. Another new message was randomly selected from the database when an irrelevant message was discarded from the sample, so as to keep the sample size at 2,000.

Classification Schema Development

A topic-based classification schema was developed based on TGCQ [14,15] and LMCC [19]. The categories of clinical related questions (including diagnosis, treatment, management, epidemiology, and their narrower terms) were mainly selected from TGCQ, while the categories of non-clinical questions (such as healthy lifestyle and health provider choosing, and their narrower terms) were mainly selected and expanded from LMCC. We divided some categories into more specific sub-categories so as to code the specific information needs. For instance, the diet category, under healthy lifestyle, was further divided into five tertiary categories, including how to eat, food choosing, interactions, action mechanism, and general.

One of the authors (specialized in medical informatics), classified all the 2,000 sample questions following the classification schema. During the manual classification progress, some categories were added to accommodate questions that did not fall into any existing medical or non-medical specialty. We developed a list of annotation rules and enumerated some general question types for each of the smallest category, so as to improve consistency among coders and the usability of the classification. For example, questions as the following types were coded as 1.1.1.1 (diagnosis→interpretation of clinical finding→symptom):

- I have (or somebody else has) symptom x, what's the condition / matter? (我有（某人有）症状X，是什么情况？ / 是怎么回事？)
- What cased symptom x? (是什么引起症状X？)
- What's the cause of symptom x? (症状X的原因是什么？)

The website (xywy.com) provides a template for users to generate question including three parts: (1) *describe your health status (病情描述)*, (2) *treatments or tests in the past (曾经的治疗或检查情况)*, and (3) *what kinds of help do you want (想得到怎样的帮助).* This template might lead to consumers' confusion on question fill-up. To deal with this case, we developed a rule: if there is the phrase "what kinds of help do you want (想得到怎样的帮助)" in the message, then code the first question after the phrase as the main topic, and successively code the questions followed by as minor topics. Otherwise, we coded the first question in the message as the main topic.

In this way, we developed the preliminary classification schema of consumer health questions, which had 101 topic categories and 32 annotation rules. The classification schema and questions coding was then modified by the following steps:

Firstly, four volunteers (two with medical education backgrouds, the others with informatics backgroud) used the classification to independently code 200 questions randomly selected from the sample, and each volunter made suggestions to specify the rules and increase some categories to accommodate the questions. The author compared the consistency of the five coding results (including the result of herself), and categorised the 200 questions into three groups: all annotators agreed on the topic (n=73), only one annotator disagreed (n=63), and more than one annotator disagreed (n=64). Then we focused on the last group, looking for problematic and ambiguous questions. Analysis of these inconsistencies allowed us to address ambiguous elements in the classification via specifying annotation rules and changing the description of the example general question types.

Secondly, the revised classification was distributed to the five annotators who independently annotated another 300 questions randomly selected from the remaining 1,800 samples. This step was done to measure the interrater reliability of the revised classification schema, as well as to modify it further.

Lastly, the three volunteers annotated the remaining 1,500 messages. Each of them annotaed 500 independently to ensure all of the 2,000 sample messages were annotated by at least two annotators. The codes agreed upon by this step were regarded as the final ones. Then we calculated the number of questions in each topic category, and deleted categories that did not have any questions filled in (e.g. physical characteristics of drugs, pharmacodynamics, mechanism of drug action).

Statistical Analysis

Descriptive analysis was used to calculate the frequency of question topics (main topic only, and all topics respectively). The kappa=$(P_o-P_e)/(1-P_e)$ statistic, which could correct agreement that occured by chance, was used to determine the interrater reliability of the question classification, where P_o was the observed agreement and P_e was the agreement expected by chance. When the number of categories was large, as in this study, P_e would be close to zero, and the kappa value would be close to P_o. Thus we directly used P_o as kappa value. The bigger the kappa value, the better the agreement. We supposed that when the user asked more than one question, it was acceptable to answer any one of them. Therefore, a liberal reliability criteria was used; a match was recorded if either the main or minor topics assigned by one annotator matched the other's assignment.

We merged the topic classification of consumer health questions developed in this study and the Taxonomy of Generic Clinical Questions (TGCQ) [15] into one classification table, and then used a chi-square test to compare the frequency distributions of topics asked by consumers and professionals.

Results

Classification of Consumer Health Questions

The final classification schema was a four hierarchical levels of specificity, consisted of 48 quaternary categories (Table 1), and included 35 annotation rules, down from 101 categories in the preliminary version. The first level included seven broad areas: diagnosis, treatment, management, epidemiology, healthy lifestyle, health provider choosing, and other. Condition/finding management questions asked what steps to take without distinguishing between diagnostic steps and

therapeutic steps [15]. To answer them, one should first give a diagnosis, and then the suggestion of treatment. A branching structure of secondary, tertiary, and quaternary levels describes more and more specific topics of the questions. One or more closely related generic questions were listed for each quaternary category. For instance, the question "A 65-year-old man with unsteady high blood pressure, what's the best blood pressure drug to eat? (65岁老人血压高经常不稳定，吃哪种降压药最好?)" would be coded as 2.1.2.1 (treatment→drug therapy→efficacy/ indications→treatment), and the generic question type could be "Condition y, what's the best drug (to eat / take / use)?"

Table 1 – Classification of consumer health questions.

Code	Primary	Secondary	Tertiary	Quaternary	Frequency(%) (main code)	Frequency(%) (all codes)
1.1.1.1	diagnosis	interpretation of symptom			39(2.0)	44(1.7)
1.1.2.1		clinical finding	sign		146(7.3)	152(5.8)
1.1.3.1			test finding		7(0.4)	8(0.3)

General Topics of Questions Asked by Health Consumers

The 2,000 sample messages were coded with 2,000 main codes and 610 minor codes, the frequency of each topic category was shown in Table 1. 48% of the questions were asked about treatment, which indicated that nearly half of the health consumers posting questions on the website have noticed that they or somebody they care about has had some health problem and needed to be treated. Almost half (45.9%) of the treatment questions were referred in particular to drug

therapy, including how to use drugs (5.6%), how to choose drugs for a particular condition (31.5%) and adverse effects of drugs (6.2%). 23.8% of the questions were asked about diagnosis, and the majority (19.4%) were seeking interpretation of consumers' specific clinical findings in reality as each pertained to the symptom they felt (1.7%), the sign they knew from physical examination (5.8%), or multiple kinds of findings they got (11.6%). 5.2% of the questions were coded as 3.1.1.1 (management of condition or findings) because they were not specified in diagnosis or treatment, and more than half of them (54.4%) were just enumerated as a series of clinical findings without any interrogative sentence or term.

11.9% of questions were asking what to do or what not to do in everyday life in order to keep healthy or get well from certain illnesses. More than half (58.4%) of them were concerned with diet or nourishment. Among the 9.0% of epidemiological questions, 5.7% were about risk factors, both risk factors of the diseases they had and if their condition would be harmful to some particular conditions, e.g., pregnancy, parturition and sexual life. 3.1% of questions were about prognosis and we thought many of them were mainly expressing anxiety as the asker wanted to get an affirmative reply to allay their worry [19]. Among the 1.9% provider choosing questions, half were about medical department choosing for specific conditions or clinical findings, which indicates that medical guide service would be a promising area for health websites.

Interrater Reliability

The kappa statistic for the five coders was 0.63 in the quaternary level of the classification, indicating "substantial" reliability. When just the the primary and secondary levels were considered, the kappa value increased to 0.75. When only the seven broad areas in the primary level were considered, agreement was almost perfect (kappa=0.82).

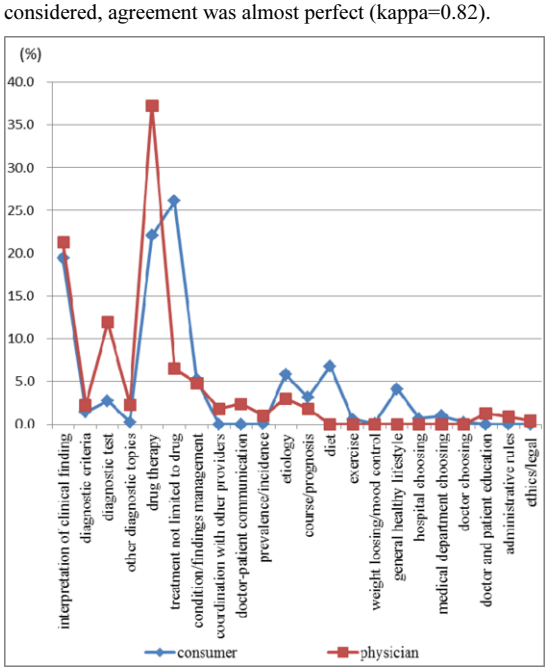

Figure 1 – The frequency distribution of the secondary topics of the questions asked by health consumers and physicians.

Difference of Health Information Needs Between Consumers and Physicians

The chi-square test of the topic distributions of the questions asked by the two groups respectively showed that health information needs of consumers were significantly different from clinical information needs of physicians. The pearson chi-square value on the quaternary category was 1477.89 ($P<0.0001$), and was 854.38 ($P<0.0001$) on the secondary category. Figure 1 shows the frequency difference along the secondary topics of the questions between health consumers and physicians. For exmaple, phyicians are more interested in the diagnosis test than consumers (11.9% vs. 2.8%).

Discussion

Health consumers and physicians both asked questions about diagnosis, treatment, management of conditions and findings, and epidemiology. Besides these topics, health consumers also asked how to keep healthy or help recovery in daily life, because many of them recognized that lifestyle, such as diet, exercise, weight loosing, and mood control, would impact their health status as well [21]. While physicians seldom asked these questions during a patient encounter, it might be because they mainly focused on medical service rather than lifestyle advice [18]. Similarly, health consumers never asked questions about coordination with other providers, doctor-patient communication, doctor and patient education, administrative rules, ethics, and legal issues, since these tasks were usually regarded as health providers' responsibility.

Both of the two groups sought answers for the interpretation of clinical findings, while the questions posted by health consumers were much more vague, the frequency of questions with multiple findings were two times more than that of physician-based inquiries. It might be because they could not distinguish which findings were most important, so they tended to put all the findings they knew. Physicians were more concerned ahout what test to choose for a particular situation and when or how to do it (the question frequency was three times more than that of health consumers), because they wanted to know how to diagnose [14,15], while health consumers wanted to know the diagnosis. Though the frequency of treatment questions was almost equal in the two groups (48.2% vs. 43.7%), physicians' questions were more specified to drug therapy (37.2% vs. 22.1%), and they sometimes asked those questions on very specialized sides, such as composition, pharmacodynamics, action mechanism, and serum levels of drugs, which were rarely asked by health consumers.

Health consumers were mainly concerned about what was wrong with their health (or the health of someone they care about), what went wrong, how to treat it (including choosing which provider to treat), possible adverse drug effects, cross interactions or dangers with other conditions (e.g. pregnancy, breast feeding, etc.), duration of recovery from the illness, and health maintenance in everyday life (e.g. dietary suggestions). Thus, they seldom asked questions that were commonly regarded as the physicians' tasks or too medical specialized.

Conclusion

This study built a classification schema of consumer health questions which consisted of 48 quaternary categories and 35 annotation rules. Five annotators followed this schema and

classified 2,000 questions randomly selected from nearly 100,000 hypertension-related messages posted by consumers on a Chinese health website. The potential uses of this study were identified as follows. First, the classification could be used to organise large collections of consumer health questions, so as to improve retrieval efficiency. Second, the distribution of question topics could be used to guide the building of a knowledge base for health websites, such as setting priorities to building a knowledge base for those frequently asked questions. Third, the coded questions could be used as a corpus for studies, such as training machines to automatically classify the topics of questions posted by health consumers, and further used for the monitoring of hot health topics and automatically generating answers. Last, but not least, the perceived information needs of health consumers could be used to help set the priorities of medical research and patient education.

This study also had some limitations, the sample questions were collected from only one website and defined to be hypertension or blood pressure related; thus, the applicability of the classification on other settings has yet to be studied further. The information needs analyzed in this study were "user based," that is, the topics were assigned without considering the best way to answer it. Although we achieved substantial interrater reliability, surpassed several similar research, such as assigning topics to generic clinical questions (kappa=0.53) [15], and assigning medical subject headings and subheadings (MeSH terms) to journal articles (consistency percentages was 0.43%) [22], the classification and annotation rules have yet to be modified and tested with larger and more diverse sample questions.

Abstract

With the recent and intensive research in the biomedical area, the knowledge accumulated is disseminated through various knowledge bases. Links between these knowledge bases are needed in order to use them jointly. Linked Data, SPARQL language, and interfaces in Natural Language question-answering provide interesting solutions for querying such knowledge bases. We propose a method for translating natural language questions in SPARQL queries. We use Natural Language Processing tools, semantic resources, and the RDF triples description. The method is designed on 50 questions over 3 biomedical knowledge bases, and evaluated on 27 questions. It achieves 0.78 F-measure on the test set. The method for translating natural language questions into SPARQL queries is implemented as Perl module available at http://search.cpan.org/~thhamon/RDF-NLP-SPARQLQuery

Keywords:

Natural Language Processing; SPARQL; Linked Data; biomedical domain; semantic resources; frames; Knowledge Databases.

Introduction

The knowledge bases (KBs) that record existing biomedical knowledge are becoming increasingly available, although they are spread over different life-science KBs that usually focus on a specific data type: chemical, pharmacological, and target information on drugs in Drugbank [1]; clinical studies [2]; drugs and their side effects in Sider [3]; etc. Creation of connections between these knowledge bases is an important research area [4]. This is indeed crucial for obtaining a more comprehensive view and is also required for producing new knowledge from the already available data. The knowledge encoded in the KBs and dataset interlinks are usually represented as RDF triples, on the basis of which the linked data can be queried through a SPARQL end-point. However, it remains difficult for typical users of such knowledge sources (mainly physicians and life-science researchers) to manage the syntactic and semantic specificities of the SPARQL language together with the structure of various KBs. In order to be able to efficiently use such KBs it is necessary to design friendly interfaces that mediate the technical and semantic complexity of the task, and to provide simpler approaches for querying the KBs. It has been shown that natural language interfaces may provide the best solution [5]. The main challenge is then to propose efficient methodologies for an easy and reproducible rewriting of natural language questions in SPARQL queries.

We present a method for transforming natural language questions into SPARQL queries, and their application to biomedical Linked Data. The method is based on the use of Natural Language Processing (NLP) methods and semantic resources for enriching questions with specific annotations. Questions are then translated in SPARQL with a rule-based approach. For designing the proposed approach, we use questions proposed by the QALD challenge task 2 [6] and additional questions for evaluation. We work with three KBs (Drugbank, Diseasome, and Sider) and can address questions related to, for instance, drug composition and properties, the related disorders, and adverse effects of drugs.

We first present the related work. We describe the proposed method and semantic resources available and developed for processing and translating the questions. We then present the results obtained and their evaluation.

Related work

It is possible to distinguish two kinds of objectives: design methods that transform natural language questions in SPARQL queries [7-8], and design methods that perform this transformation and also execute the queries over Linked Data. In both cases it is necessary to define the user interface that hides the underlying structure of the knowledge bases and the SPARQL syntax. We investigate the second purpose, which also provides the possibility to properly evaluate the methods and the results obtained. Three possibilities are usually explored for querying the Linked Data [8]: Knowledge-Based Specific Interface, Graphical Query Builder, and Question-Answering System. It has also been demonstrated that, for this task, the use of natural language is preferred to the use of keywords, menus, or graphs [6]. Among the existing work, we can mention the use of Question-Answering systems on 50 questions from DBpedia proposed by the QALD-2 challenge, that gives 0.62 average F-measure obtained with 39 questions. Average recall for these 39 questions is 0.63 and average precision is 0.61, although 11 questions cannot be covered by the templates [9]. Studies exploring KBs that describe general language are frequent [10-11], although there are some studies on processing biomedical KBs. For instance, experiments have been proposed on translation of medical questions from a journal into SPARQL queries. This work combined the SVM machine learning-based approach with patterns to generate the SPARQL queries. The evaluation was carried out on 100 questions and the corresponding queries were tested on clinical documents. The method achieved 0.62 precision [12].

Materials

Questions and reference data are provided by the Question Answering over Linked Data (QALD) challenge 2014 [13], dedicated to retrieval of biomedical information in linked KBs with questions in natural language. This question set is composed of 50 questions which we use for setting up the methods. We create 27 additional questions for testing the method. Examples of the questions processed include:

- Which foods does fluvoxamine interact with?
- Are there drugs that target the Probable arabinosyltransferase A?
- Which genes are associated with subtypes of rheumatoid arthritis?
- Which disease has the highest degree?
- Which targets are involved in immune function?

Our method relies on existing biomedical resources with semantic entities data, and on additional resources collected and built for supporting the method. The steps of the method are described in the next section.

Domain-Specific Resources. We use three biomedical resources to process the question set: Drugbank, Diseasome, and Sider. Drugbank http://www.drugbank.ca is dedicated to drugs [1]. It merges chemical, pharmacological, and pharmaceutical information from other available biomedical KBs. We exploit the documentation [14] of this resource to define the rewriting rules and regular expressions for the named entity recognition. Diseasome [15] is dedicated to diseases and genes linked among them by known disorder/gene associations [16]. It provides a single framework with all known phenotypes and disease gene associations, indicating the common genetic origin of many diseases. We exploit the RDF triples and documentation of the resource to define the rewriting rules. Sider [17] is dedicated to adverse drug effects [18]. It contains information on marketed medicines and their recorded adverse drug reactions. Information is extracted from public documents and package inserts and provides side effect frequency, drug and side effect classifications, and links to other data such as drug-target relations. The content of each resource is provided in specific format: RDF triples *subject predicate object*. For this reason, we can exploit their RDF schema to define frames.

Additional Resources for Question Annotation. On the basis of the RDF triples, frames are built from the RDF schemas in which the RDF predicate is the frame predicate, and the subject and object of the RDF triples are the frame elements. This also includes the OWL *sameAs* triples. Several types of frame entities are isolated:

- Subject, object, and predicate from triples become semantic entities. They may occur in questions. In this way, the frames are the main resource for rewriting questions in queries;
- The vocabulary specific to questions is also built. It covers, for instance, aggregation and negation operators and types of questions;
- RDF literals, issued from named entity recognizer or term extractor, complete the resources. RDF literals are detected with specifically designed automata that rely on the source KB documentation.

These entities are associated with the expected semantic types, which allows creating the queries and rewriting the RDF triples in the SPARQL queries. In that respect, we can consider internationalized resource identifiers (IRI), strings, common datatypes, or regular expressions when literals are expected. Most of the entities are treated through their semantic types, although some ambiguous entities (e.g., interaction or class) are treated atomically. For these, the rewriting rules are applied contextually to generate the semantic entities corresponding to the frames. During the query construction step, semantic types become variables and are used for connecting the edges of queries.

Methods

The method is rule-based and is composed of five parts: linguistic and semantic annotation of questions, question abstraction, query construction, query execution, and evaluation. We demonstrate the main steps of the method with the question, *Give me drugs in the gaseous state*. The method is based on NLP tools and methods and must respect constraints of the SPARQL syntax.

Linguistic and Semantic Annotation of Questions is performed in several steps: identification of numerical values (corresponding to numbers or solubility index, for instance) with a named entity recognizer; parsing of questions in words; part-of-speech tagging and lemmatization of questions with TreeTagger [19] (Figure 1); and annotation of semantic entities (terms and their associated semantic types) with the TermTagger Perl module [20] and semantic resources like disease names and side effects (Figure 2). In order to complete the coverage of semantic resources, we use the term extractor YaTeA [21-22] for the identification of noun phrases.

Figure 1 - Linguistic annotation of questions.

Figure 2 - Semantic annotation of questions.

In the *Question Abstraction* step the objectives are to identify relevant elements within questions and to build a representation of these elements (Figure 3). This step relies on linguistic and semantic annotations. For instance, the word *drug* receives the semantic type *Drugs* from Drugbank. The main difficulty is that some entities may receive conflicting or concurrent semantic types. The purpose is then to select those semantic types that are the most correct and useful for the next steps. This is done as follows:

- We keep larger terms which do not include other semantic entities;
- We define and apply rewriting rules on the training set in order to modify or delete semantic types associated with a given entity according to the context;
- We also modify or delete entities according to their context. For instance, the semantic entity *interaction* must be rewritten in *interactionDrug1* if the mention

of drug is found in its context, but it has to be rewritten in *foodInteraction* if a term with the semantic type *food* is found in its context.

We define a set of 44 contextual rewriting rules based on vocabulary used in questions from the training set and on the documentation of KBs, mainly of Drugbank [14]. After this processing, the identification of relevant elements can be performed more safely. After the identification of relevant elements, we perform the question abstraction, for which we identify information related to the structure of query (i.e., question topic, result form, predicate and arguments, scope of negation, and conjunctions):

- The first entity with the semantic type that is provided by the RDF subjects and objects issued from the resources is considered to be the question topic. This information is used for the query construction. The question topic in Figure 3 is identified as *drug*;

Agregation operator:			
Question topic:	drug (drugbank/drugs)		
Predicates:	Frame		
	drugbank/drugs	state	STRING
Arguments:	Semantic type	Word	SPARQL type
	drugbank/state/Gas	gaseous	STRING/Gas

Figure 3 - Identification of relevant elements in questions.

- For the definition of the result form, the question is scanned in order to identify words expressing negation (e.g. *no*), aggregation operation on the results (e.g. *number* for *count*, *mean* for *avg*, *higher* for *max),* and specific result forms such as boolean queries (*ASK).* At this step the linguistic expressions are associated with the corresponding SPARQL operators. Information extracted at this step is recorded and used for the query construction. In the example in Figure 3, no such information is found;
- Identification of Predicate and Argument: we use linguistic representation of the RDF schema, i.e., frames that contain one predicate and at least two elements with associated semantic types. The potential predicates, subjects, and objects of frames are identified among the semantic entities and recorded: entries are the semantic types of the elements and refer to linguistic, semantic and SPARQL information associated with these elements. Subjects and objects are described with inflected and lemmatized forms of words or terms, the corresponding SPARQL types, and indicators on their use as object or subject of a predicate. Concerning the predicates, only semantic types of their arguments are instantiated. Subjects and objects can be URI, RDF typed literals (numerical values or strings), and extracted terms (these are considered as elements of regular expressions). In Figure 1, the predicate *state* with the expected arguments *drugbank/drugs* and *Gas/String* is recognized.
- Scope of negation and conjunctions: Argument and predicate in the neighborhood of negation and conjunctions are identified. These elements are recorded as negated or coordinated.

Agregation operator:			
Question topic:	?v0		
Predicates:	Frame		
	?v0	state	STRING/Gas
Arguments:	Semantic type	Word	SPARQL type
	drugbank/state/Gas	gaseous	STRING/Gas

Figure 4 - Construction of queries.

The objective of the *Query Construction* step is to connect previously identified elements and to build a semantic representation of the SPARQL graph pattern (introduced by the keyword *WHERE).* Figure 4 presents the architecture of the connection of elements and query construction. Thus, the predicate arguments are instantiated by URIs associated with the subjects, objects, variables, and numerical values or by strings. For each question, we perform several connections:

- The question topic is connected to the predicate(s). A given variable is associated with the question topic and with the predicate argument that matches the semantic type of the question topic. Note that at the end of this step, the question topic may remain unassociated with a predicate. In Figure 4, variable *?v0* represents the association between the question topic and the subject (with the expected type *drugbank/drugs*) of the predicate *state;*
- The predicate arguments are connected to subject and objects identified during the question abstraction: they concern elements referring to URI. Moreover, each predicate within the conjunction scope is duplicated and its arguments are also connected to the subject and objects if needed;
- The predicates are connected between them through their subjects and objects. The connection between two predicates is also represented by a variable;
- The predicates from different datasets are connected. We use the *sameAs* description to identify URIs referring to the same element. New variables are defined to connect two predicates;
- The remaining question topic is connected to arguments of the *sameAs* predicate;
- The arguments corresponding to the *string* type are connected with the extracted terms that are considered as string expressions. They are connected through the string matching operator *REGEX.*

At this point, the predicate arguments which remain unassociated are replaced by new variables in order to avoid empty literals. Finally, the negation operator is processed: the predicates are marked as negated and the arguments within the negation scope are included in a new predicate *rdf:type* if required. At this step, each question is fully translated into a representation of the SPARQL query. Figure 5 illustrates the construction of the query.

```
SELECT DISTINCT ?v0
WHERE {
?v0 <http://www4.wiwiss.fu-berlin.de/drugbank/resource/drugbank/state>
"Gas".
}
```

Figure 5 - Construction of queries.

Query Generation is a syntactic step, during which the query is formed syntactically. The SPARQL query representation

built during the query construction step is used to generate the SPARQL query string. The process is composed of two steps:

- Generation of the result form which takes into account the expected type of the result form *(ASK* or *SELECT*), the presence of aggregation operators, and the variable associated to the question topic;
- Generation of the graph pattern. This step consists of generation of strings for representing each RDF triple and defining a SPARQL filter if the predicates are negated. When aggregation operators are used, we also need to recursively generate sub-queries for computing the subsets of expressions, before their aggregation. In example from Figure 1, the predicate *state* is replaced by the corresponding URI and its object is replaced by the string *gas*.

The SPARQL queries have been submitted to a SPARQL end-point. For these experiments, we use the SPARQL end-point provided by the QALD-4 challenge [23] and answers are collected for the evaluation.

Evaluation Metrics. The generated SPARQL queries are evaluated through their answers with three macro-measures [24] shown in Figure 6. *TP(q)* are the correct answers, *FP(q)* are the wrong answers and *FN(q)* are the missing answers for the question *q*. The use of macro-measures equally considers all the questions independently of the number of expected answers to the SPARQL queries. The comparison is done with the answers obtained through the manual querying of KBs.

$$M_{\text{precision}} = \frac{\sum_{i=1}^{|q|} \frac{TP(q)}{TP(q)+FP(q)}}{|q|}$$

$$M_{\text{recall}} = \frac{\sum_{i=1}^{|q|} \frac{TP(q)}{TP(q)+FN(q)}}{|q|}$$

$$M_{\text{F-measure}} = \frac{2 \times M_{\text{precision}} \times M_{\text{recall}}}{M_{\text{precision}} + M_{\text{recall}}}$$

Figure 6 – Macro-measures for evaluating SPARQL queries

Results

Global Results. Table 1 indicates the overall results obtained on the training and test sets. On the test set, the macro-F-measure is 0.78 with 0.81 precision and 0.76 recall while on the training set, the macro-F-measure is 0.86 with 0.84 precision and 0.87 recall. Each question is processed in less than 2 seconds on a standard computer (2.7GHz dual-core CPU and 4 Gb of memory). Most of the computing time is spent for the linguistic and semantic annotation of the questions.

Table 1 - Results obtained with the training and test sets.

Query set	Training (50 Q)	Test (27 Q)
Correct queries	39	20
Micro-precision	0.84	0.81
Micro-recall	0.87	0.76
Micro-F-measure	0.86	0.78

Discussion

Questions from the test set may involve new operators and lexicon not known from the test set. Nevertheless, our method always proposes syntactically correct SPARQL queries for all natural language questions from the training and test sets: 18 questions provide the exact expected answers, two questions return partial answers, and other questions return no correct answers. On the training set, 39 out of 05 SPARQL queries are semantically correct and provide the expected answers, 6 return partial answers, and 5 return no answers. An analysis of erroneous or partial answers shows that most of the errors are due to:

- The encoding of the *sameAs* predicate in the resources. We observe that, although our method generates the correct SPARQL query, the SPARQL end-point does not return the expected answers. Besides, we observe that the correct answers can be obtained by switching the arguments of the *sameAs* predicate in the queries. It appears thus that the instances of this predicate do not encode the expected reflexivity of this relation in the source KBs while our method assumes that the *sameAs* predicate is reflexive by definition;
- The management of ambiguities in questions. The errors due to ambiguities are mainly related to (1) the annotation of semantic entities and (2) the expected meaning of terms in the questions. Related to (1) annotation, in the question, *Which genes are associated with breast cancer?*, *breast cancer* is correctly annotated, while the reference data propose that it is to be associated with the semantic entity *Breast cancer-1*. Related to (2) expected meaning,. semantic entities that occur in some questions may refer to specific entities while in other questions they refer to general entities. For instance, the semantic entity *anemia* in *What are enzymes of drugs used for anemia?* refers to all types of anemia (*Hypercholanemia*, *Hemolytic anemia*, *Aplastic anemia*, etc.) and not to the elements that contain the label *anemia.*

We defined and described some rules for managing the ambiguities, but they must be completed with additional rules. For instance, these two main problems can be solved by using regular expressions in SPARQL graphs rather than URIs. However, we must test the influence of this modification on the whole set of queries. Other erroneous answers happen during the question abstraction step when the question topics are wrongly identified or when the contextual rewriting rules cannot be applied. Errors also occur during the query construction step. The method may abusively connect predicate arguments and semantic entities or, on contrary, it may not consider all the identified semantic entities. Further investigations have to be carried out to solve these limitations.

During the design of queries, we may also have difficulties to express some constraints in SPARQL. For instance, the question, *Which approved drugs interact with calcium supplements?,* requires defining a regular expression with the term *calcium supplement* while this term is only mentioned in conjunction with other supplements (*e.g., Do not take calcium, aluminum, magnesium or iron supplements within 2 hours of taking this medication.*). We assume that solving this difficulty requires more sophisticated NLP processing of the textual elements of the RDF triples: parsing the RDF textual

elements, named entity and term recognition, identification of discontinuous terms and term variants, etc. When a sufficient quantity of questions and corresponding queries is available, some regular expressions used in the current work can be replaced by machine learning approaches in order to make a generalization of the named entity detection, or for the detection of semantic relations and operators.

Other limitations are related to KB updates and changes to their structure. In the former case it is required to rebuild the semantic resources used for identifying the semantic entities. In the latter case the entire frames must be regenerated. This is ongoing research work. Moreover, the possibility of adding new resources, such as Dailymed [25] or RxNorm [26], is a related problem. When managed, this functionality will allow processing new linked datasets with low adaptation cost.

Conclusion

We proposed a rule-based method to translate natural language questions into SPARQL queries. The method relies on linguistic and semantic annotations of questions with NLP methods, semantic resources, and RDF triples description. We designed our approach on 50 biomedical questions proposed by the QALD-4 challenge and tested it on 27 newly created questions. The method achieves good performance with 0.78 F-measure on the set of 27 questions. Future work aims to address the limitations of our current method including the management of term ambiguity, question abstraction, and query construction. Moreover, to avoid the manual definition of the dedicated resources required by our approach (frames, specific vocabulary, and rewriting rules), we plan to investigate how to automatically build such dedicated resources from the RDF schemas of the Linked Data set. It will also facilitate the integration of other biomedical resources such as Dailymed or RxNorm, and the use of our method in text mining applications.

Abstract

Operative notes contain essential details of surgical procedures and are an important form of clinical documentation. Sections within operative notes segment provide high level note structure. We evaluated the HL7 Implementation Guide for Clinical Document Architecture Release 2.0 Operative Note Draft Standard for Trial Use (HL7-ON DSTU) Release 1 as well as Logical Observation Identifiers Names and Codes (LOINC®) section names on 384 unique section headers from 362,311 operative notes. Overall, HL7-ON DSTU alone and HL7-ON DSTU with LOINC® section headers covered 66% and 79% of sections headers (93% and 98% of header instances), respectively. Section headers contained large numbers of synonyms, formatting variation, and variation of word forms, as well as smaller numbers of compound sections and issues with mismatches in header granularity. Robust operative note section mapping is important for clinical note interoperability and effective use of operative notes by natural language processing systems. The resulting operative note section resource is made publicly available.

Surgical Procedures, Operative; Vocabulary, Controlled; Medical History Taking/methods; Quality and Safety; Documentation; Electronic Health Records

Introduction

Operative notes are traditionally created at the completion of a surgical procedure by the primary surgeon who recalls the procedure details and dictates these into a narrative that is subsequently transcribed. Effective operative note documentation is important for assessing surgical quality (1), billing and medico-legal issues (2, 3), and other secondary uses of operative notes (4). With increasing adoption of electronic health record (EHR) systems, operative notes and other clinical documents are increasingly generated and immediately available. EHR systems also enable other mechanisms for note generation, including voice to text software, typed notes, synoptic reporting, and templated notes.

Synoptic reports are used to create documents with discrete data fields whereby desired information from the note can be collected, stored, and retrieved in a standardized fashion. In contrast, templated notes range in the amount of structure that they contain, including some having highly prescriptive and structured formats to others having mostly free-text narrative with primarily document section structure alone. While dictation and transcription remains the most common mechanism for operative note creation, synoptic reports and templates are increasingly used in surgery for operative report creation and appear to encourage improved completeness of these documents (5, 6). Independent of the mechanism used to create the document, section headers in operative notes provide high level structure and serve as "containers" which provide context to the text within the given section (7).

Previous research has examined section headers in clinical notes, with some work exploring the task of automated classification of sections in documents. As an initiative with the OpenGALEN project, Mori et al. utilized "tags" in 5 clusters (Nature, Safety Context, Interpretation, Intention, and Organization) and evaluated this approach to classify 600 section headings (7). Denny et al. reported on a terminology of document sections in "history and physical" (H&P) notes and developed an associated section terminology with Logical Observation Identifiers Names and Codes (LOINC®) mappings (8). These authors later developed an algorithm, "SecTag", to identify and label section headers and section boundaries in H&P notes. Similarly, others have utilized predefined sections to aid in a number of natural language processing tasks, such as problem list extraction and named entity recognition (9-11).

In the United States, H&P note formats are largely governed by Evaluation and Management (E/M) documentation, which provides guidelines for assessing adequacy of documentation for each patient encounter resulting in a "level of service" and justification for a patient bill (12). Operative notes, in contrast, are not covered by E/M, and the Joint Commission (13) and Centers for Medicare & Medicaid Services (CMS) (14) have specified criteria for operative notes including information on suggested contents and note sections. Overall, Joint Commission designates eleven required elements for operative notes: name(s) of primary surgeon/ physician and assistants, pre-operative diagnosis, post-operative diagnosis, name of the procedure performed, findings of the procedure, specimens removed, estimated blood loss, date and time recorded, indications for the procedure, intra-operative complications, and a full description of the procedure.

The Health Level 7 (HL7) Structured Documents Workgroup seeks to develop structured healthcare document standards to promote document and data interoperability. This group has created implementation guides for clinical documents including one for operative notes, the Implementation Guide for HL7 Clinical Document Architecture (CDA) Release 2.0, Operative Note Draft Standard for Trial Use Release 1 (HL7-ON DSTU) (15). This specification includes Level 1 (header constraints), Level 2 (section level constraints of the structuredBody of the ClinicalDocument), and Level 3 (entry

level constraints within a section; specifying only the Plan section of Operative Notes) requirements. The HL7-ON DSTU was created using a variety of data sources and expert opinions including subject matter expert input, summary statistics from sample operative notes, Joint Commission Operative Note Requirements: Standard IM.6.30 (13), and CMS Operative Note Requirements (14). Where possible, the HL7-ON DSTU utilizes existing clinical statement entries and Continuity of Care Document (CCD) elements, and other Implementation Guide templates. As such, some items considered clinical statement entries in other contexts are treated as sections. The HL7-ON DSTU also maps section headings using LOINC® where available.

To improve available resources and tools for clinical natural language processing[1] specifically for operative reports (16, 17) and using our experience with clinical standards evaluation (18-20), we sought to use the HL7-ON DSTU and LOINC® section codes to represent operative note section headers and to develop a resource for operative note section headers.

Materials and Methods

Study Overview

Figure 1 provides a high level summary of this study. The HL7-ON DSTU was examined and section headers with associated LOINC® codes were collected along with potential document section headers from LOINC®. In this case, LOINC® was used as the clinical terminology for mapping section headers, which are considered an observation or measurement. Although the Systematized Nomenclature of Medicine--Clinical Terms (SNOMED CT) contains many clinical concepts, section headers and document names are not represented. All operative notes over a 4-year period from University of Minnesota-affiliated Fairview Health Services, which includes an academic medical center, one children's hospital, four community hospitals, and three ambulatory surgery centers, were collected from a full range of general surgery and surgical subspecialties, and section headers were extracted. Headers were mapped and coded to eliminate non-section headers, assess section header variation, and identify granularity issues with mapping to structured sections. The section headers and mappings were combined into a resource. Institutional review board approval was obtained and informed consent waived for this minimal risk study.

HL7-ON DSTU Section Header Extraction

Level 1 and Level 2 HL7-ON DSTU constraints were used in this evaluation. Level 1 header elements included information commonly contained in sections for operative notes (e.g., "Primary Performer" - typically referred to as the "Surgeon" or "Primary Surgeon" in operative notes is a header element). Required and optional operative note section names were used along with LOINC® section mappings, section descriptions and suggested information about each item. Level 3 constraints were excluded from the analysis as were Level 1 header elements not related to section headers (such as elements to encode the overall operative note specification).

In addition to the HL7-ON DSTU section headers, LOINC® section header names, codes, and descriptions were collected by extracting entries of "DOCUMENT_SECTION", resulting in 121 distinct sections from LOINC® Version 2.42. Unmapped terms with this list were also mapped to "CLASS" entries of "H&P.HX", "H&P.HX.LAB", "H&P.PX", or "H&P.SURG PROC" with free text search in a second step.

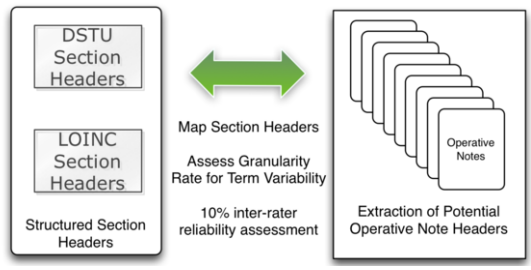

Figure 1 – Overview of Study

Operative Note Section Header Evaluation

Potential operative note section headers were automatically extracted using heuristic rules including the use of capitalization, semi-colons and hyphens, and line-breaks. Frequencies of each potential header were calculated and a cut-off of 100 was used in coding headers. The eliminated set of headers accounted for less than 2% of overall entries.

Each header was then manually designated as a document title, a potential section header, or not a potential section header by two coders. Potential section headers were then mapped to a HL7-ON DSTU standard section name and the provided LOINC® section specification, if available. Table 1 provides an overview and examples of section header codings.

Table 1 – Coding for Operative Note Section Headers

Coding and Explanation	Example(s)
Not a Section Header: *term is not a known section header or document title*	"See Radiology Report From"; "Operating Room"
Document Title: *term is a document title*	"Brief Operative Note"; "Operative Report"
Document Header Information: *term is other document information*	"Patient Identification"; "Dept"
Correct Section Header: *term is preferred section in* HL7-ON DSTU	"Anesthesia"; "Complications"; "Surgery Description"
New Section Header: *term not in* HL7-ON DSTU	"Cross-Clamp Time"; "Preoperative History"
Synonym: *term is alternate synonymous section name (new or known section)*	"Surgery Description" (*Preferred)* vs. "Operation Description"
White-Space, Formatting, Misspelling: *white-space, formatting, or misspelling*	"Post-operative" vs. "Postoperative"
Word Form Variant: *term is word form variant to preferred or synonym term*	"Preoperative Diagnosis" vs. "Preoperative Diagnoses"
Abbreviation: *term is an abbreviation*	"EBL" vs. "Estimated Blood Loss"
Compound Section Header: *two or more sections designated*	"Operative Indications and Consent"

Same Granularity: *term has same granularity as mapped header*	"Specimens" vs. "Specimens Removed"
Less Granularity: *term has less granularity than mapped header*	"Diagnoses" vs. "Postoperative Diagnosis" or "Preoperative Diagnosis"
More Granularity: *term has more granularity than mapped header*	"Arthroscopic Findings" vs. "Findings"

Each extracted potential section header name was then coded to designate if the header was: the preferred section header name; a new section header from the HL7-ON DSTU; a synonym; had white space, misspelling, or formatting variation; a word form variant; an abbreviation; a compound section header; or a header with additional granularity compared to the HL7-ON DSTU suggested section header specifications. Mapped entries were compared to the section name and coded according to their granularity as: equal, greater, or less granularity. Finally, if a section header could not be mapped to the HL7-ON DSTU, the section header was mapped to LOINC® (21).

Approximately 10% of all mappings were evaluated by both coders (a surgeon and informatician (GM) and a surgeon and informatics graduate student (EA)) in order to assess inter-rater agreement. Percent agreement and Kappa were calculated for mappings to document titles, non-section headers, and section headers; coding for HL7-ON DSTU section headers; and assessment for entry variation (e.g., word forms and synonyms).

The section headers and subsequent mappings were used to create a resource of operative note section headers to improve the reuse of these notes. The resource contains section header terms, term mapping to HL7-ON DSTU and LOINC, and information granularity of mappings.

Results

HL7-ON DSTU Section Header Extraction

Operative note section names and LOINC® section mappings for all designated sections in the HL7-ON DSTU were collected. This included 3 main header elements related to operative note sections which resolved to 6 potential section elements, 12 section names (8 required), and 4 subsection names (all options). Table 2 contains example entries for these 18 elements from the HL7-ON DSTU.

Table 2 –Operative Note Sections from HL7-ON DSTU

Section	LOINC Code	Component Name
Consent (O, H)	N/A	CONSENT FOR SURGICAL PROCEDURE
Anesthesia (R, Sec)	8724-7	SURGICAL OPERATION NOTE ANESTHESIA
Indications (O, Sec)	10217-8	SURGICAL OPERATION NOTE INDICATIONS
Implants (O, Sub)	55122-6	SURGICAL OPERATION NOTE IMPLANTS

R:required;O:optional;H:header;Sec:Section; Sub:Subsection

Operative Note Section Header Evaluation

Automated extraction of headers from 362,311 operative note section resulted in 2,999,414 entries. Removal of entries with a frequency of less than 100 (n=52,054) resulted in 2,947,360 (98.3%) total entries and 476 unique entries.

Initial coding demonstrated that 8 headers (6,975 instances) were document titles, 7 headers (15,525 instances) were document header information, and 77 headers (26,189 instances) did not represent valid potential section headers (Table 3). Of the remaining 384 section headers (2,898,771 instances), 66% section headers (93% instances) mapped to the DSTM and after including LOINC® sections for the remaining elements, successful mappings were obtained for 79% of headers (98% of instances). We also observed large numbers of synonymous terms, normalized variants and other formatting associated with section headers.

Table 3 – Operative Note Section Header Findings

	Headers N (%)	Instances N (%)
Overall	476 (100)	2,947,360 (100)
Document Title	8 (2)	6,875 (0.2)
Header Information	7 (1)	15,525 (0.5)
Not a Section Header	77 (16)	26,189 (0.9)
Section Header	384 (81)	2,898,771 (98)
Map to HL7-ON DSTU	255 (66)	2,735,563 (93)
Granularity		
Same Granularity	179 (70)	2,132,446 (78)
Greater Granularity	65 (25)	594,605 (22)
Less Granularity	11 (4)	8,512 (0.3)
Variation in Terms		
Normalized Word Form	63 (25)	328,090 (12)
Formatting Variation	18 (7)	318,233 (12)
Synonyms	177 (69)	1,203,053 (44)
Abbreviation	18 (7)	256,103 (9)
Map to HL7-ON DSTU or LOINC®	304 (79)	2,833,094 (98)
Mapping Failure	80 (21)	65,677 (2)
Multiple Sections	22 (28)	10,607 (16)
No Mapping	58 (72)	55,070 (84)

Table 4 summarizes mappings to the HL7-ON DSTU including numbers of terms mapping to different headers and the proportion of terms that mapped with equal granularity. There was significant variability in expression for many HL7-ON DSTU section headers, and differences in granularity particularly for section headers for primary performer and secondary performer. An analysis of the 30 most common section terms mapped to the HL7-ON DSTU in all but one case, and the remaining header was a LOINC® section mapping (data not pictured).

Table 4 – HL7-ON DSTU Section Header Mappings

Total Headers	Unique Headers	Section Name	Same Granularity
211,303	4	Anesthesia	99.8%
93,408	6	Complications	100%
16,898	10	Disposition	58.5%
115,307	5	Estimated Blood Loss	100%
2,945	7	Implants	100%
197,127	20	Indications	100%
18,192	20	Operative Note Fluids	79.9%
565,596	33	Operative Note Surgical Procedure	100%
22948	11	Plan	88.8%
283	1	Planned Procedure	100%
327,151	13	Postoperative Diagnosis	100%
333,307	14	Preoperative Diagnosis	99.7%
203,494	21	Primary Performer	0%*
383,174	31	Secondary Performer	0%*
32,530	15	Specimens Removed	99.6%
100,374	28	Surgery Description	100%
1,100	2	Surgical Consent	100%
22,208	2	Surgical Drains	100%
86,415	11	Surgical Operation Note Findings	99.5%
484	2	Surgical Date of Procedure	100%
1319	2	Surgical Procedure Duration	100%

In the overlap coding of 50 entries, percent agreement and Kappa for the initial mapping of document titles, non-section headers, and section headers was 100% and 1.00; the HL7-ON DSTU mapping agreement for section headers mapping was 92% and 0.94, respectively.

A number of section headers did not map to the HL7-ON DSTU or LOINC® section headers. A number of these appeared to be unique to operative notes such as “Tourniquet Time”, “Sponge and Needle Counts”, “Bypass Time”, “Preoperative Antibiotics”, and “Preoperative Status”.

Discussion

As the demand for the extraction of meaningful information from more challenging clinical data sources such as clinical texts becomes an area of greater focus, operative notes and other clinical documents will be reused for a variety of purposes. These efforts aid quality improvement, research, and ultimately clinical data interoperability. This study examines a structured document standard for operative notes, which includes Level 1 (Header) and Level 2 (Section) specifications. Section headers from the HL7-ON DSTU and additional LOINC® sections headers were evaluated on headers extracted from a large number of operative notes from an integrated healthcare delivery system. The standards covered most header instances although amongst unique headers, about 20% did not map. We also observed a large amount of variation in the section header term expression including many synonyms, formatting variations, variation in word forms, and compound section headers within the corpus. Although the large variability of expressions in section headers was not altogether, unexpectedly due to the known variety of expressions commonly seen in clinical text, this was an interesting observation in that the overall section header number was large even for headers, which are generally considered semi-structured and more constrained.

While the HL7-ON DSTU provides eight required section names and a small number of main header items that are conventionally sections in operative notes, our study demonstrates the wide variability in expressions of these elements, the frequent use of optional sections, including the 8 section/subsection elements designated in the HL7-ON DSTU as well as 49 section headers designated in LOINC® and not in the HL7-ON DSTU and 58 section headers unique to both the HL7-ON DSTU and LOINC®. As the HL7-ON DSTU authors note, the base specification for an operative note, like other clinical documents, is the HL7 CDA, Release 2.0, allowing for other sections not present in the HL7-ON DSTU to occur in operative notes. Further, despite the significant challenges with variability in expression of section headers present in our corpus, the “exact text of the section names are not mandated” by the HL7-ON DSTU.

Several of the unique sections that did not map to the HL7-ON DSTU or LOINC®, including “Tourniquet Time”, “Sponge and Needle Counts”, “Bypass Time”, “Preoperative Antibiotics”, and “Preoperative Status” may be valid optional section headers. Some of these are important elements for operative notes for certain subspecialties (e.g., cardiac surgery, transplant surgery, or vascular surgery). Further assessment of operative note sections in other hospital systems may also be helpful for establishing the generalizability of the results of our study.

We also observed issues with respect to both granularity as well as variability in expressing different section headers. In particular, the section header “Disposition” which is standard to the HL7-ON DSTU had a number of entries that were more granular than the general header, including “Postoperative Condition” or “Prognosis”. Similarly, both “Primary Performer” and “Secondary Performer” had wide amounts of variability to the amount of detail expressed. “Primary Performer” included more granular terms such as “Attending Neurosurgeon” and less granular terms such as “Physician”, which is under specified enough that it is unclear whether this represents a Primary Performer or not. Similarly, “Secondary Performer” had mostly more granular terms, many of which were trainees including residents and fellows, as well as the designation of assistants and other providers involved with procedures.

With respect to variability in section header expression, many terms including “Operative Note Surgical Procedure” and “Surgery Description” had many terms to express the same section header. This was similarly the case with “Primary Performer” and “Secondary Performer”, as just described. Surprisingly, sections like “Indications” and “Operative Note Fluids” also had wide variability with 20 different section terms for these two section headers each. We observed that while “Operative Note Fluids” is the section recommended for operative notes, surgeons were sometimes to describe the more significant resuscitative elements like blood products

and colloid administration and instead used ad hoc section headers like “Components Used”.

While the majority of the section headers were fully specified by their name, there were some section headers where the content of the associated section was ambiguous. For instance, the section header “Procedure” or “Procedure(s)” in most cases designates “Operative Note Surgical Procedure”, which lists the procedure(s) performed by the surgeon, similar to the “Surgical Procedure” (Header) which provides coded enumeration of the procedures performed. However, in some cases, the section “Procedure” can be the section most commonly labeled with the operative note section “Surgery Description”, which described the procedure in detail. The disambiguation of these headers may be addressed in future studies at the semantic level with the contents of operative notes using machine-learning or other automated approaches. This also points out the large amount of variability in expression and practice with operative note composition.

There are several limitations to this study. Section headers were extracted from operative notes using a set of deterministic section segmenting rules, and some were likely missing in our analysis. Additionally, while comprehensive in sample size and having data created from academic and community sites, the study was conducted within a single regional hospital system composed of six hospitals including an academic hospital, a children’s hospital, four community hospitals, and three ambulatory surgical centers. The study’s findings could be further validated in a future corroborating study.

Conclusion

Structured document standards and well-formed section header designations are important for interoperability of clinical documents and natural language processing systems that consume these documents. We evaluated the HL7-ON DSTU specification for operative note section headers and LOINC®. Our findings confirm that most section headers are covered by the HL7-ON DSTU and LOINC®. However, there is a large amount of variability in section header expression, and a number of section headers specific to operative notes not currently present in these resources. These findings should be considered for future HL7-ON DSTU iterations and possibly for addition to LOINC®. The resulting section header resource can also be used for section header mappings for natural language processing systems.

A Process for the Representation of openEHR ADL Archetypes in OWL Ontologies

Alex Mateus Porn[a], Leticia Mara Peres[a], Marcos Didonet Del Fabro[a]

[a] *Informatics department, Federal University of Paraná, Brazil*

Abstract

ADL is a formal language to express archetypes, independent of standards or domain. However, its specification is not precise enough in relation to the specialization and semantic of archetypes, presenting difficulties in implementation and a few available tools. Archetypes may be implemented using other languages such as XML or OWL, increasing integration with Semantic Web tools. Exchanging and transforming data can be better implemented with semantics oriented models, for example using OWL which is a language to define and instantiate Web ontologies defined by W3C. OWL permits defining significant, detailed, precise and consistent distinctions among classes, properties and relations by the user, ensuring the consistency of knowledge than using ADL techniques. This paper presents a process of an openEHR ADL archetypes representation in OWL ontologies. This process consists of ADL archetypes conversion in OWL ontologies and validation of OWL resultant ontologies using the mutation test.

Keywords:

Archetypes, ADL, Ontologies, OWL.

Introduction

An archetype is a formal expression of a distinct concept in the domain level, expressed as constraints on data whose instances are in accordance with the reference model. The development process of an archetype consists mainly of translating a clinical concept for Reference Model entities, defining structure and data representation in an Electronic Health Record (EHR) [28]. Information sources for its development are varied: expert knowledge, specialized publications, data entry screens and system reports, term lists, clinical system data models, messages and regulatory forms, and forms used in clinical appointments or medical records [7, 8].

Clinical archetypes developed according to the openEHR [16] model use the Archetype Definition Language (ADL) as a standard [26]. This language presents an abstract syntax that can be used to express archetypes based on any information model. However, it presents difficulties in implementation and a few available tools to manage contents [3].

Although ADL language has its own syntax, it can be described using other languages such as eXtensible Markup Language (XML) [27] and Web Ontology Language (OWL) [10], increasing the integration with other Semantic Web tools and decreasing interoperability problems between health information systems [3, 4]. Therefore, processes for exchanging and transformating data can be better implemented with semantics oriented models, such as ontologies using OWL [1].

Ontologies define terms to describe and represent a knowledge domain. They are descriptions of concepts and relationships that can be used by people or software agents to share information in this domain. So, they can be used as a unifying structure for semantic representation of information [17, 18].

Ontologies have been frequently used to represent biomedical knowledge in recent years [12, 13]. They provide strict structures for knowledge management tasks related to archetypes and EHR systems representation [3].

We define in this article a process for the representation of ADL archetypes in ontologies described in OWL (or OWL ontologies) which are validated using mutation test. This process has two steps: the conversion of ADL archetypes in OWL ontologies using the algorithm of Elkin et al. [14] and the validation of OWL ontologies using the mutation test of Porn et al. [19, 20].

Archetype Definition Language (ADL)

ADL is a formal language to express archetypes, where the structure is independent of standard or domain. In general, it is not a language for clinical domains. It can be used to define any type of archetype for different reference models therefore it is possible to represent the same syntactic structure among diverse models [1].

ADL archetype is basically composed of three sections [1, 9]: (1) the section *header,* which contains the name of the archetype, a unique code that identifies the clinical concept and information of specialization and the language in which it was written; (2) the *definition* section, which specifies the structure and constraints associated with the clinical concept, restricting the cardinality and the content of the instances of the information model; (3) and the *ontology* section, which represents terminological definition to each clinical concept. In this paper only the d*efinition* section of archetypes is used to the conversion process to OWL.

ADL has some difficulties in implementation. When performing semantic processing two elements are required: one ADL parser and one parser of the reference model to ensure clinical accuracy of content [1].

The ADL parser produces a set of objects without explicit semantic relations among them. The semantics are unknown to the parser and only the association among the elements of *Definition* and *Ontology* section can be defined [1]. Thus, ADL reasoning possibilities are currently very limited [3], as well as the availability of tools to manage ADL contents is reduced. Consequently, the formalization of exchanging data and data transformation processes among systems becomes more difficult than using semantics oriented models, such as OWL ontologies.

Ontology Web Language (OWL)

An alternative to problems related to ADL language is the archetypes representation through OWL ontologies. OWL allows definitions that are meaningful, detailed and accurate with consistent distinctions among classes, properties and

relations defined by the user [1]. Thus, the construction of archetypes using OWL can ensure the consistency of knowledge in a more general way than when using ADL techniques due to the lack of tools for managing these models.

The OWL language is used to define and instantiate Web ontologies and is defined by the W3C (World Wide Web Consortium) [10]. OWL ontology specifies how to derive logical consequences through the formal semantic OWL, clarifying facts that are not presented in the ontology but are bounded by the semantics [11].

Ontologies impose strict structures to knowledge management related to archetypes and EHR systems [3], so that several methodologies and tools have been proposed to compare different ontologies, mixing and identifying inconsistencies. Thus, activities such as comparison, selection, classification and consistency checking can be performed in the OWL in an easier and more efficient way than in the ADL content. As a matter of fact, OWL is a knowledge representation language.

The use of ontologies to represent biomedical knowledge is not a new process, as ontologies have been used in biomedical domains in recent years in different purposes [12, 13]. Thus, OWL becomes appropriate to represent clinical archetypes and information about EHR, so that constraints on archetypes can be determined by OWL or by defining appropriate elements.

Materials and Methods

For the representation of ADL archetypes in OWL ontologies two steps were established:

1. Convert openEHR archetypes developed in ADL language to OWL ontologies, based on an algorithm for mapping ADL objects to OWL, adapted from a model proposed by Elkin et al. [14].
2. Validate OWL ontologies obtained after conversion. For this, OWL ontologies are tested using mutation tests [19, 20].

Figure 1 shows an example of *definition* section of an openEHR archetype implemented in ADL language, that will be converted to an OWL ontology.

```
definition
    EVALUATION[at0000] matches {    -- A health oriented check list
        data matches {
            ITEM_TREE[at0001] matches { -- Tree
                items cardinality matches
                {1..*; unordered} matches {
                    CLUSTER[at0004] occurrences matches
                    {1..*} matches {    -- Question group
                        items cardinality matches
                        {1..*; unordered} matches {
                            CLUSTER[at0002] occurrences matches
                            {1..*} matches {    -- Question
                                items cardinality matches
                                {1..2; unordered} matches {
                                    ELEMENT[at0003] matches {*}
                                    ELEMENT[at0005] occurrences matches
                                    {0..1} matches {    -- A comment on the answer
                                        value matches {
                                            DV_TEXT matches {*}
                                        }}}}}}
                    ELEMENT[at0006] occurrences matches
                    {0..1} matches {    -- Summary
                        value matches {
                            DV_TEXT matches {*}
                        }}}}}
```

Figure 1 – Definition section of an ADL archetype

To represent archetypes in OWL, it is necessary to define in OWL the classes from the Reference Model used by the archetype. Thus, the following algorithm is used to the first step of the conversion process:

1. Reference Model classes used by the archetype are represented as OWL classes;
2. Each archetype node defined as a clinical concept is represented as a subclass of one of the classes of the Reference Model used;
3. Object properties that define associations among nodes and archetype components are defined as OWL Object Properties. The domain declaration of this properties is indicated for the archetype class itself, and the range declaration to the set of objects that should be associated to the domain of this property;
4. Properties that represent data structures in ADL are defined as OWL Data Type Properties, being the domain declaration indicated as the cardinality of objects associated to this property, and the range declaration defined as the data types of all objects found in the archetype with respect to this attribute;
5. Properties constraints and cardinalities defined in ADL archetype are converted in constraints and axioms of OWL language.

Basically, an archetype has a hierarchical structure and constraints started with a root class. Thus, for an ADL archetype that presents several archetype nodes of the Reference Model of the same type, as ELEMENTs, in OWL just one class is defined to represent this node as a root class of the hierarchy and the clinical concepts of the archetype are represented as subclasses of these classes of the Reference Model.

Based on the conversion algorithm, it is possible observe at Figure 2 the definition of the archetype nodes EVALUATION, ITEM_TREE, CLUSTER and ELEMENT of the Figure 1, represented as OWL classes.

```
<Declaration>
    <Class IRI="#CLUSTER"/>
</Declaration>
<Declaration>
    <Class IRI="#ELEMENT"/>
</Declaration>
<Declaration>
    <Class IRI="#EVALUATION"/>
</Declaration>
<Declaration>
    <Class IRI="#ITEM_TREE"/>
</Declaration>
```

Figure 2 – openEHR Reference Model classes in OWL

In the hierarchy of an ADL archetype, properties that define associations among archetype nodes, refer to Information Reference Model classes, therefore they associate individuals of classes from a lower level, to individuals of classes from a higher level, defining classes and subclasses from the archetype [44]. Figures 3 to 7 show excerpts of one OWL ontology representing each structure of ADL archetype of Figure 1. Figure 3 presents OWL Object Properties which represent the properties that define associations among nodes and components of the ADL archetype.

```
<Declaration>

    <ObjectProperty IRI="#value_matches"/>
    <Class IRI="#Answer"/>
</ObjectPropertyRange>
<ObjectPropertyRange>
    <ObjectProperty IRI="#value_matches"/>
    <Class IRI="#Summary"/>
</ObjectPropertyRange>
```

Figure 5 – Range Definitions of OWL Object Properties

It is possible to observe in Figure 6 the definition in OWL of the properties that represent data structures in ADL from Figure 1, with domain and range declarations of these properties defined as shown for OWL Object Properties.

```
<Declaration>
    <DataProperty IRI="#value_matches_A_comment_on_the_answer"/>
</Declaration>
<Declaration>
    <DataProperty IRI="#value_matches_Summary"/>
</Declaration>
<Declaration>
    <DataProperty IRI="#value_matches_answer"/>
</Declaration>
```

Figure 6 – ADL Operators as OWL Data Type Properties

As ADL data properties are represented as OWL Data Type Properties according to the conversion algorithm, associations can be made through OWL constructors *hasValue*, *someValuesFrom* and *allValuesFrom*.

So, according to the last step of the conversion algorithm, ADL property constraints and cardinalities are defined as OWL constraints, as shown in Figure 7 the constraints concerning the ELEMENT and ITEM_TREE classes of the archetype from Figure 1.

```
<EquivalentClasses>
    <Class IRI="#ELEMENT"/>
    <ObjectIntersectionOf>
        <ObjectSomeValuesFrom>
            <ObjectProperty IRI="#items_cardinality_matches_question"/>
            <Class IRI="#Question"/>
        </ObjectSomeValuesFrom>
        <ObjectSomeValuesFrom>
            <ObjectProperty IRI="#items_cardinality_matches_tree"/>
            <Class IRI="#Tree"/>
        </ObjectSomeValuesFrom>
    </ObjectIntersectionOf>
</EquivalentClasses>
```

Figure 7 – ADL constraints as OWL constraints

The conversion process and the resulting representation of ADL archetypes to OWL were assisted by a tool for creating and editing of ontologies called Protégé [15]. The following steps were defined:

1. Manual selection of openEHR ADL archetypes in the online repository CKM [16]. Seven archetypes in the review state were selected. Three archetypes are OBSERVATION type, respectively the “Apgar score”, “Autopsy examination” and “Fetal heart rate” archetypes. Two are EVALUATION type, the “Alert” and “A health oriented check list” archetypes. One is INSTRUCTION type and one is an ACTION type, respectively “Informed consent request” and “Follow up action” archetypes.
2. Manual conversion of ADL archetypes to OWL based on the conversion algorithm, being the process realized with the aid of Protégé tool;

To validate archetypes and reveal possible defects inserted in OWL ontologies (proposed in step 2 of the process), we applied the mutation test technique to OWL Ontologies [19, 20].

Results

OWL ontologies obtained after the conversion process are readable for humans and computers, facilitating the interpretation of clinical concepts as well as the development of queries and content management.

Test methods which validate OWL models help to ensure adequacy and quality in ontologies. Tests allow the representation of knowledge domain with security and accuracy. Written queries in SPARQL [25] or DL Query [21] can be used to validate the correction of syntactic and semantic structures in tests of instantiation, recovery, achievement, satisfaction and classification [22].

Published studies have shown that mutation test is the most effective in revealing defects [23, 29]. Mutation test is a defect-based technique proposed in [19, 20, 24] to simulate defects on ontologies, generating mutant ontologies, according to predefined mutation operators known. Mutant ontologies must reveal defects or be considered equivalent (non defective) to the original ontology, according to the DL Query test data used.

After seven openEHR ADL archetypes have been selected in the online repository CKM and converted to OWL, it was possible to generate a total of 2000 mutants ontologies and 187 defects in all OWL ontologies [20].

Detailing in the “Apgar score”, “Autopsy examination” and “Fetal heart rate” archetypes were found respectively 41, 19 and 44 defects. In the “Alert” and “A health oriented check list” archetypes were found 16 and 21 defects and, in the “Informed consent request” and “Follow up action” archetypes revealed 31 and 15 defects. 139 mutant ontologies were defined as equivalent to the original ontology and other mutants were killed with test data generated.

Discussion

Archetypes are used to guide clinical practice, requiring the exploration, comparison, classification and integration of information originating from different heterogeneous systems. The OWL language presents excellent mechanisms for these activities, enabling the representation of ADL archetypes in OWL ontologies and providing an excellent semantic representation of the clinical concepts addressed.

The representation of archetypes in OWL requires the semantic interpretation of clinical archetype, so that the ADL

structures defined in the archetype specialize in openEHR Reference Model classes [9]. Therefore, defects can be created by the developer during the definition of the OWL archetype constraints, and these defects can cause failures. This was possible to observe with the reached results after the application of the mutation test technique in the archetypes was represented in OWL.

It is also possible to observe with the reached results, the large number of mutants generated, determining a high possibility of occurrence of defects in the development. However, the existence of defects in obtained models does not characterize problems in the conversion process. This is because OWL ontologies are based on open world assumption, thus the representation of archetypes in OWL requires the semantic interpretation of clinical archetype.

The purpose of applying the mutation test technique was to validate the obtained results after the conversion process, in this case OWL ontologies, and not the conversion process proposed. Consistently selected archetypes in the online repository CKM were in their review state. Defects were found after the conversion process in OWL ontologies; however, this did not invalidate the proposed method of conversion ADL archetypes to OWL ontologies.

In some cases it was not possible to identify the defect applied by the mutation operator with any given test data because it was not considered in this analysis the instantiation of objects for each archetype classes represented in OWL, which might produce better results. The mutants of these cases are defined as equivalents.

For 139 mutants that have been defined as equivalent, it would be possible to obtain better results (that is, it is possible to define whether the ontology has or not defects) executing the mutant ontologies with same test data and instantiating individuals to ontology classes. Moreover, it can be concluded in these cases that the test data used were not efficient, because they do not produce distinct results from the original ontology and there is the possibility of generating new test data.

With the application of the mutation test on the archetypes in OWL, it is possible to validate the models obtained after the conversion process due to the identification of committed defects, correcting and ensuring the correction of the archetype.

Conclusion

Ontologies define concepts, classes, properties, relationships, constraints and axioms about a particular knowledge domain, which can represent the real and conceptual world through semantic identifiers. Ontologies have proven to be extremely useful to assist the development of computer systems, due to some of their own characteristics such as vocabulary for representing knowledge and the possibility for extending a generic model for a specific domain.

A clinical archetype represents a specific knowledge domain and can be modeled in ontologies in different ways. It was proposed in this paper to convert clinical archetypes of the openEHR standard implemented in ADL to OWL ontologies. In the conversion process, two steps were defined: (1) the conversion from ADL to OWL; (2) the validation of the model obtained.

The ontology developed tool Protégé was used to perform the first step of conversion process of openEHR archetypes to OWL ontologies as well as to perform the second step of process, where it was applied the mutation test in the OWL ontologies obtained. For each mutation performed, it generated a new ontology defined as mutant. For the generation and execution of test data, it used the DL Query language, a query language for ontologies available on the Protégé tool.

For this experiment, seven openEHR archetypes were used, generating an average of 285 mutants to each model. From the total of mutants ontologies obtained, 187 defects were identified and 139 mutants were defined as equivalent to the original ontologies. Each defect revealed in a mutant ontology corresponds to mutation performed by a mutation operator. The analysis and correction were made based on the characteristics of this known mutation operator.

The conversion process was experimented. A test method determined the correction of resulting OWL ontologies. A high number of mutants was generated and defects were revealed, consistent with the fact that they were under review. It is also possible to infer that this test method can be applied to other knowledge domains represented by OWL ontologies.

Harmonizing SNOMED CT with BioTopLite: An Exercise in Principled Ontology Alignment

Stefan Schulz[a], Catalina Martínez-Costa[a]

[a]*Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Austria*

Abstract

The integration of heterogeneous ontologies is often hampered by different upper level categories and relations. We report on an on-going effort to align clinical terminology/ontology SNOMED CT with the formal upper-level ontology BioTopLite. This alignment introduces several constraints at the OWL-DL level. The mapping was done manually by analysing formal and textual definitions. Descriptive logic classifiers interactively checked mapping steps, using small modules for increasing performance. We present an effective workflow, using modules of several scales. However, only part of the classes and relations could easily be mapped. The implications for future evolution of SNOMED CT are discussed. It seems generally feasible to use a highly constrained upper-level ontology as an upper level for the benefit of future SNOMED CT versions that are more interoperable with other biomedical ontologies.

Keywords:

Biological Ontologies; SNOMED CT.

Introduction

The support of domain terminologies by formal ontologies is increasingly seen as an important requirement for semantic interoperability in health care and biomedical research. The integration between clinical and research data is essential for the advance of translational and personalized medicine. Both health care and biomedical research have terminology systems. Whereas the Unified Medical Language System (UMLS) [1] has focused on the integration of heterogeneous terminology systems in terms of lexical semantics, the discipline of Applied Ontology [2] has proposed to look beyond linguistic and conceptual structures. Applied Ontology's attention focuses on the referents, i.e., the entities denoted by terms and concepts, their ontological nature and the way they are related. Description logics (DLs) [3], especially the different OWL dialects [4] have become de-facto standards for ontologies.

An important aspect is the standardization of ontology artefacts in terms of upper-level ontologies**,** i.e., formal or semi-formal systems of categories, relations and axioms, linked to human-readable labels. The development of the two most well established upper-level ontologies, namely DOLCE [5] and BFO [6], focused on certain areas like cognitive sciences (DOLCE) and natural science (BFO). Other examples for upper-level ontologies in the biomedical domain include the GALEN upper level [7], the UMLS semantic network [8], and the OBO relation ontology RO [9].

The OBO Foundry effort [10] advocates the use of upper-level ontologies. In parallel, the ontological foundations of the large clinical terminology SNOMED CT [11] have substantially evolved, and the important field of medical classifications, with ICD as flagship, will be increasingly anchored in ontological grounds [12]. Whereas OBO Foundry ontologies are aligned with BFO 1.1 classes and with relations from RO, SNOMED CT's ontological framework is largely influenced by the legacy of former SNOMED versions, together with a frame-like concept model, which evolved almost untouched by formal-ontological deliberations.

An ontological upper-level shared by a range of different domain ontologies would have several advantages:

- Upper-level ontologies would force the categorization of domain entities into well-defined upper level categories. This is not at all trivial, regarding the inherent ambiguity of many legacy categories. A typical example is the pseudo-category *Problem*, a key concept in clinical documentation and decision-making, e.g., as single items that constitute clinical problem lists. *Problem* includes a broad range of statements on a person having a disease now or in the past, having a certain behaviour, having a history of surgical interventions etc., together with epistemic aspects like severity, significance, certainty, priority etc.
- Medical terms that denote what is commonly classified by *Disease* / *Disorder* turn out to be ambiguous [13]. For example, "allergy" may denote a disposition or a process, "fracture" may denote a damaged anatomical entity, but also the fracturing event, or even the life phase during which an organism exhibits the former and which has started with the latter.
- Upper-level ontologies would standardize the ways entities are related with each other. This standardization means a well-defined canon of relations. However, this situation requires a consensus about the precise meaning of relations, in terms of their algebraic properties and relation hierarchies, such as whether the relation **is part of** is reflexive, or whether **is part of** always implies **is included in**. The fact that important relations are ternary (e.g., *a* **is part of** *b* **at time** *t*), whereas the commonly used representation languages are binary is an issue not to be neglected [14]. This fact also complicates the current process of creation of an OWL version out of the upper level ontology BFO2 [15].
- Upper-level ontologies introduce constraining axioms that enforce conformance with domain ontologies that depend on them. Examples include domain / range constraints, such as that only members of the class *Process* can be in the domain of the relation **has participant**, but also further-reaching constraints such as that material entities can have material or immaterial entities as parts, whereas processed can only have processes as parts.

In this paper, we report on a first pilot of a harmonization effort that aims to fill the gap between SNOMED CT and other biomedical ontologies. We use the domain level ontology BioTopLite2 (BTL2) [16] in order to align SNOMED CT with well-defined classes and relations, and we use BTL2's rich set of axioms for validating the design decisions. Finally we will test the scalability of the map by measuring classification time, given that SNOMED CT mapped to BTL2 means to go from polynomial to exponential complexity.

Methods

SNOMED CT is gaining ground as an international clinical terminology standard. After the fusion of earlier SNOMED nomenclatures with the UK clinical terminology CTV3, the international standards organisation IHTSDO has embraced the mission of transforming SNOMED CT into a global healthcare language. Although the ontological SNOMED CT content, to date, is primarily released in relational format, a standard way of creating Description Logics (DL) axioms out of them has been described. This algorithm has been implemented in Perl script, from which the description logics axioms can be generated as an OWL-EL ontology [11]. The DL version has primarily been used to automatically generate taxonomic links in the SNOMED CT production process.

Table 1 shows the concepts of the uppermost level of the SNOMED CT concept hierarchy, under which all of the approximately 300,000 SNOMED CT concepts are grouped.

Event	*Situation with explicit context*
Observable entity	*Social context*
Organism	*Special concept*
Pharmaceutical/biologic product	*Specimen*
Physical force	*Staging and scales*
Physical object	*Substance*

Table 2 shows the most frequent relations (object properties) in the OWL version (out of 62). These relations account for approximately 95% of all asserted relational statements in SNOMED CT axioms (totalling approx. 380,000).

Table 2 –most frequent SNOMED CT relations

Role group	**Direct device**
Finding site	**Direct substance**
Method	**Using substance**
Associated morphology	**After**
Procedure device	**Has specimen**
Has active ingredient	**Has focus**
Causative agent	**Finding context**
Has dose form	**Associated finding**
Interprets	**Has intent**
Procedure site - Indirect	**Procedure site**
Direct morphology	**Using access device**
Component	**Procedure context**
Has interpretation	**Associated procedure**
Occurrence	**Access**
Using device	**Specimen source topography**
Temporal context	**Laterality**
Subject relationship context	**Associated with**

BioTop was launched in 2006 as an Upper Domain Ontology in OWL DL. As BioTop never intended to compete with established ontologies, its developers created bridging ontologies to DOLCE, BFO, RO, and the UMLS Semantic Network and left the uppermost level deliberately flat. An important asset of BioTop has been its strong focus on constraining axioms, as an important mechanism for consistency checking, which is not yet available for BFO and RO. BioTop was used as a domain top level in several projects [16]. Later, a reduced form was released, named BioTopLite. Its classes and relations are shown in Tables 3 and 4.

Table 3 – BioTopLite2 upper classes

Disposition	*Process*
Function	*Quality*
Immaterial object	*Role*
Information object	*Temporal region*
Material object	*Value region*

Table 4 – BioTopLite2 upper relations (OWL object properties, without inverses, without descendants)

at some time	**includes**
causes	**precedes**
has condition	**projects onto**
has participant	**represents**

The **mapping process** was done for all SNOMED CT concepts and relations in Table 1 and 2. The use of the complete SNOMED CT OWL version for this exercise would have resulted in severe performance problems, slowing down the whole process.

We therefore decided to perform the mapping on modules of SNOMED CT. One type of modules (M1) was constructed based on signatures that contained one seed concept per SNOMED CT pattern. We defined a SNOMED pattern as a generalization of a subclass or equivalence axioms in the sense that each concept in the axiom was substituted by its uppermost ancestor, i.e., the concepts in Table 1. This method yielded 1,746 axiom types[1]. For each axiom type, a concept was selected randomly. The resulting set of concepts was used as a signature to create a module by following all outgoing links horizontally and vertically, according to [17]. Such a module has about 11,000 classes (variations resulting from random selection have only minor effects). Another series of modules (M2) was created from weighted (by subhierarchies) random signatures of different sizes.

The mapping was done completely manually, following previous work, employing an iterative approach [18,19]. The decision for a given map was done by thoroughly analysing the meaning of the candidate classes and relations, considering formal axioms as well as text definitions and hierarchical context. Each major ontology mapping step is checked by a DL reasoner, the results of which are then analysed and corrected under two perspectives: first, the classes tagged as 'inconsistent' are identified and the causes are investigated and repaired; second, whenever the ontology has reached a consistent state, the logical entailments are analysed for adequacy. Again, the causes are investigated and fixed, whenever wrong

1 Duplications of clauses like '**rel**$_m$ some *TopConcept*$_n$' were ignored; '**rel**$_m$ some *TopConcept*$_n$ and **rel**$_o$ some *TopConcept*$_p$' vs. '**rel**$_o$ some *TopConcept*$_p$ and **rel**$_m$ some *TopConcept*$_n$' and other variations in order were only counted once.

entailments were encountered. We used Protégé 5 [20] for editing, together with the HermiT [21] and FaCT++ reasoners [22], supported by the included explanation facility [23].

Results

The mapping of the classes yielded the following results (BioTopLite classes are indicated by the namespace prefix btl:, SNOMED CT by sct:)[2]:

- **Equivalence mapping** was possible only for the class sct:*Organism*.
- **Simple subclass mappings** were done for the following SNOMED CT top-level concepts: sct:*Event* under btl:*process*, sct:*Observable entity*, *Record artefact* and sct:*Staging and scales* under btl:*information object*, sct:*Pharmaceutical / biologic product*, sct:*Physical object* and sct:*Specimen* under btl:*polymolecular composite entity*, sct:*Physical force* under btl:*quality*, sct:*Procedure* under btl:*action*.
- **Complex subclass mappings**, i.e., those targeting compositional BTL2 expressions were done for sct:*Body structure*, which was mapped to the expression btl:*immaterial object* or btl:*structured biological entity*. Target for sct:*Clinical finding* was the expression btl:*disposition* or btl:*function* or btl:*material object* or btl:*process*. This expression was introduced for convenience as the defined class btl:*condition*, due to the necessity to pragmatically deal with the ambiguous, cross-category meaning of diseases, disorders and findings. sct:*Environment or geographic location* was mapped to btl:*immaterial object* or btl:*poly molecular composite entity*. Finally, sct:*Substance* was mapped to the disjunctive statement btl:*amount of pure substance* or btl:*compound of collective material entities*, due to the fact that also mixtures at molecular or microscopic level (blood, milk) are substances in SNOMED CT.
- **No mappings** resulted from the analysis of (i) sct:*Qualifier value*, (ii) sct:*Situation with explicit context*, (iii) sct:*Social context*, and (iv) sct:*Special concept*. In the first case, we found a large inhomogeneity, including actions like *Training – action*, qualities like *Decreased*, as well as numbers and units of measurement. The second case refers to entities of the frequently debated *Situation with explicit context* hierarchy, which is a kind of SNOMED-internal information model with concepts like *No temperature symptom* or *Treatment changed*. Although most of them could be mapped to btl:*Information object*, we refrained from a mapping. (For a thorough ontological analysis of these so-called context model concepts cf. [24]). Under (iii) we have encountered roles, individual humans, as well as population groups, and under (iv) we found inactive concepts and navigational concepts, which exist only to provide nodes in a navigation hierarchy, according to [25] and are therefore of no ontological relevance.

The mapping of relations proved far more complex, because of their larger number in both ontologies (see Tables 2 and 4) and the large number of constraining axioms attached to BTL2 relations. We decided to map not only the relations at the uppermost hierarchical level but also some of their descendants, because of their frequent use and special semantics. So far, we have limited the relation mapping effort to those relations that, together, cover 95% of all relational statements in SNOMED CT, see Table 2.

Only one relation equivalence was found, namely sct:**After** for btl:**precedes**.[3]

A special case was the sct:**RoleGroup** relation, which had originated as a mere syntactic construct to circumvent nested expressions [26], and then was found to be interpretable in several ways according to its context. We identified two different possible mappings: for domains of the type sct:*Clinical Finding* the corresponding BTL relation is btl:**has condition**, domains of the type sct:*Procedure* would be mapped to btl:**has part**.

Most SNOMED CT relations could be mapped as subrelations to BTL2 relations, together with refined domain and range restrictions. This is the case with the following relations:

- sct:**Finding site** mapped to btl:**is included in** with domain btl:*condition* and range sct:*Body structure;*
- sct:**Procedure site** mapped to btl:**is included in** with domain sct:*Procedure* and range sct:*Body structure;*
- sct:**Using device** mapped to btl:**has patient** with domain sct:*Procedure* and range sct:*Physical object*;
- sct:**Causative agent** mapped to btl:**caused by** with range sct:*Substance*;
- sct:**Laterality** mapped to btl:**bearer of** with range btl:*Quality*;
- sct:**Has active ingredient** mapped to btl:**has part** with domain sct:*Pharmaceutical / biologic product* and range sct:*Substance*;
- sct:**Associated morphology** mapped to btl:**has part** with domain btl:*condition* and range sct:*Morphologically abnormal structure*;
- sct:**Has dose form** mapped to btl:**is bearer of** with domain sct:*Pharmaceutical / biologic product* and range sct: *Drug dose form*;
- sct:**Has specimen** mapped to btl:**has patient** with domain sct:*Procedure* and range sct: *specimen*;
- sct:**Method** mapped to btl:**includes** with domain sct:*Procedure* and range sct:*Qualifier value*;
- sct:**Access** mapped to btl:**is bearer of** with domain range sct:*Qualifier value*;
- sct:**Occurrence** mapped to btl:**projects onto** with domain range sct:*Qualifier value*;
- sct:**Procedure device** mapped to btl:**has patient** with domain sct:*Procedure* and range sct:*Physical object*;
- sct:**Component** mapped to btl:**has patient** with domain sct:*Procedure* and range sct:*Substance*;
- sct:**Specimen source topography** mapped to the chain (btl:**at some time** • btl:**is included in**).

[2] We use *Italics* for classes / concepts and **Bold face** for relations (object properties)

[3] Another relation pair for which equivalence mapping seems plausible is sct:**part of** / btl:**is part of**. The former is not in our list as it is, to time, is infrequent SNOMED CT**.** After the planned redesign of the anatomy branch in SNOMED CT, this will be one of the most frequent relations.

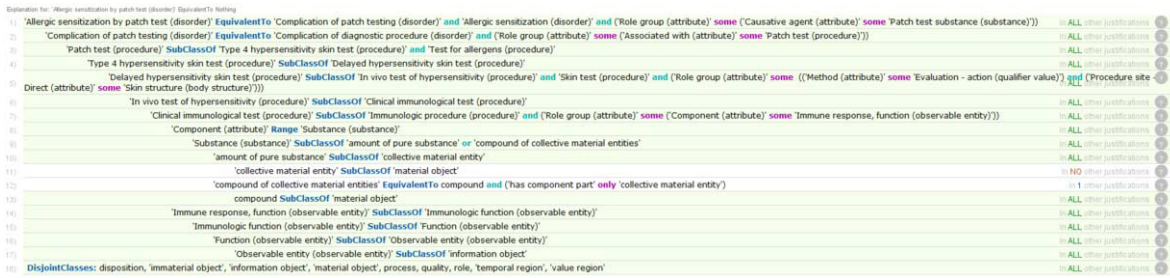

Figure 1 – Documentation of an unsatisfiable class using the Protégé explanation function

Several SNOMED CT subrelation introduce additional aspects, e.g. sct:**Procedure site - Indirect**, sct:**Direct morphology**, sct:**Direct device**, sct:**Using access device**. The differentiation of their meaning regarding their respective superrelations cannot be expressed by any BTL relation. One solution would be to assign roles or qualities to the target classes, e.g., the difference between direct or indirect surgical access.

There are complex relationships in SNOMED CT that cannot be mapped to any BTL2 relation. For instance sct:**Has focus** describes the intent of a procedure to reach a certain goal. An appropriate representation would require a model of intentionality, together with a reference to a class that is not (yet) instantiated. This would require an approach similar to the representation of plans, which is outside of what can be expressed in OWL-EL [27].

As argued in [24], the concepts in the SNOMED CT hierarchy *Situation in specific context* represent epistemic entities like components in an information model. As shown in [28], there are possibilities to express such statements in description logics, as instances of the class btl:*information object*, however requiring a more expressive logic than OWL-EL. We therefore exclude the following relations from our mapping: sct:**Finding context**, sct:**Procedure context**, sct:**Associated finding**, sct:**Interprets**, sct:**Has intent**, sct:**Subject relationship context**, sct:**Has interpretation**, sct:**Temporal context**, sct:**Subject relationship context**.

The mapping workflow turned out to critically depend on classification time. Whenever the ontology was in an inconsistent state, the classification of SNOMED CT modules of type M1 (in which all SNOMED CT patterns are represented) causes disruptions of more than fifteen minutes. In such cases, a switch to M2 modules of smaller scale was mostly sufficient for debugging, with classification times under two minutes. The debugging of insatisfiable classes was time consuming, which is illustrated by the output of the Protégé explanation function (Figure 1). At the end of the described phase, with a mapping of 95% of the relational clauses, there were on average three insatisfiable SNOMED CT concepts in modules with on average 11,050 concepts.

Conclusion

The on-going SNOMED CT – BTL2 aligning experience has shown up until now that large parts of SNOMED CT were compatible with a highly principled and compact upper level ontology like BioTopLite. The mapping at class level demonstrated a good agreement with BioTopLite for fifteen of the nineteen subhierarchy roots. That ontologically heterogeneous subhierarchies like sct:*Situation with specific context*, sct:*Qualifier value*, as well as sct:*Social context* and sct:*Special concept* could not be straightforwardly mapped was not surprising. We recommend that these SNOMED CT branches undergo a major redesign. At the level of the relations, the known ambiguity of the role group relation was confirmed. This construct requires further analysis and should eventually be substituted by a set of new relations that are clearly labelled. However, this would have to include nested relations into the SNOMED CT architecture, a desideratum that had been formulated on various occasions, by several stakeholders, such as the IHTSDO Observable group.

Regarding the other relations, SNOMED CT would be well served in most cases with a much smaller set of relations. The multitude of relations is, above all, a legacy issue. The simple BTL2 relation btl2:**is included in** would perfectly suit to substitute the SNOMED CT relations sct:**Finding Site** and sct:**Procedure Site**. The same would be true for btl:**has part**, which could substitute the relations sct:**Active ingredient** and sct:**Associated Morphology**. From an ontological point of view, we see no need to repeat the sort of the range concept (e.g., being a morphology or a substance) in the relation. This would simplify the construction and maintenance of SNOMED CT.

Although BTL2 uses the whole range of OWL-DL constructors, classification of SNOMED CT modules under BTL2 even of a size of 15,000 classes show satisfactory performance values, with about 15 minutes using the HermIT classifier. For a non-disruptive workflow it has been proven valuable to use small random modules that classify quickly after each modification of the map, because it is quite likely that the impact of a modelling error leads to insatisfiable classes even in these small modules. Once all small modules are satisfiable, then the more time consuming consistency check with a big module can be performed. Such modules that cover the complete variability of SNOMED CT by containing at least one class for each occurring design pattern have a size of approximately 11,000 classes. Checking the map with these modules might spot additional errors, or confirm the satisfiability documented by the smaller (incomplete) modules.

This approach could be integrated into the SNOMED CT maintenance and redesign workflow, which until now is mainly guided by the constraints formulated inside the frame-like SNOMED CT concept model. In contrast, the OWL version used in the production process cannot spot inconsistencies due to the inexpressiveness of the language.

In 2008, Rector and Brandt argued in favour of a more expressive description logics for SNOMED CT [29]. Our findings suggest the feasibility for this at least regarding the upper level.

Standardized Cardiovascular Quality Assurance Forms with Multilingual Support, UMLS Coding and Medical Concept Analyses

Julian Varghese[a], Sarah Schulze Sünninghausen[a], Martin Dugas[a]

[a]*Institute of Medical Informatics, University of Muenster, Germany*

Abstract

Standardized quality assurance (QA) plays an import role to maintain and develop success of cardiovascular procedures (CP). Well-established QA models from Germany could be shared in a form repository for world-wide reuse and exchange.

Therefore, we collected the complete set of all quality QA forms for CP, which is obligatory to be filled out by all German health service providers. Original forms were converted into standardized study forms according to ODM (Operational Data Model) and translated into English. Common medical concepts and clusters of medical concepts were identified based on UMLS coding of form items.

All forms are available on the web as multilingual ODM documents. UMLS concept coverage analysis indicates 88% coverage with few but critically important definition gaps, which need to be addressed by UMLS.

Keywords:

Cardiovascular Procedures; Quality Assurance; Medical Forms; UMLS.

Introduction

Cardiovascular diseases (CD) represent one of the leading causes of death in adults in the majority of developed countries [1] and are already rising in poorer populations [2]. Patients suffering from severe cases of CD, which cannot be treated solely by medication or conservative therapy, need to receive surgical or non-surgical interventions as lifesaving treatments.

Existing methods of quality assurance (QA) are necessary to measure, maintain, and further develop the medical quality of medical procedures among different health service providers. Since 2000, all German health service providers are obliged by law to apply QA for their services [3]. A distinct form-based QA documentation has evolved for 30 medical specialties containing more than four million patient cases, indicating outstanding efforts in German QA at international level [4]. This QA documentation also poses major challenges for routine hospital documentation, which already represents a significant amount of physicians' work time. The original QA-forms, which are already in use, are defined in a structured way but do not apply standardized data models.

Innovative approaches to interoperable medical forms need to be established to incorporate those forms into different hospital information systems for harmonious structured clinical data storage and linkage to routine documentation. To enforce this, it is important to use existing standard data models and semantic codes from international terminologies for data items within those forms. Thus, each data item is defined in a structured way and linked to a medical context unambiguously such that form items get machine-readable and language-independent. The first feature is beneficial for clinical data management and data analysis where electronic forms are used for medical documentation and form-based data retrieval [5]. The last feature enables the world-wide reuse of medical forms where QA is less developed.

To achieve this, international vocabularies with a large coverage for clinically relevant medical terms need to be used such that medical terms (e.g. Myocardial infarction, Dissection of aorta) can be correctly mapped semantically to data elements in the forms.

The objectives of this work are threefold:

1. Acquire all current German QA forms for cardiovascular procedures (CP) and process them into the standardized model of study forms: Operational Data Model (ODM) [6] specified by the Clinical Data Interchange Standards Consortium (CDISC) [7] and supported [5] by regulatory agencies such as Food and Drug Administration (FDA) [8] and European Medicines Agency (EMA) [9].
2. Translate German data items into English and semantic coding using the Unified Medical Language System (UMLS) [10] based on medical expert decision. All forms will be accessible on a medical form repository, which has been developed, based on our previous work [11].

   This way, we will provide the first medical E-forms for QA, with structured data items and international semantic annotations in a technical standard format and open access to enable international discussion, editing and re-use.

   Based on the English translation and the language-independent medical context of items provided by UMLS codes, further languages can be easily added.

   To give an example of our methods of form sharing and multilingual support, a clinical Follow Up form has been published previously with semantic coding and English translation, upon which currently 17 languages (German, English, French, Portuguese, Spanish, Mandarin, Hindi, Japanese, etc.) have been added [12].
3. Based on UMLS-coding of form items, frequency analysis of medical concepts is conducted to identify most frequently used concepts and clusters of concepts within the domain of cardiovascular diseases relevant to QA. Furthermore, a coverage analysis of UMLS will show the possible extent of critical concept definition gaps for medical QA.

Supplement files including full data tables and large figure images are available on:

Methods

Forms retrieval

All available QA forms for CP have been acquired from the German Institute for Applied Quality Improvement and Research in Health Care (AQUA) [13]. Permission for scientific analysis and publication was granted.

The original forms were provided as PDF files and a data model for all forms using a relational Microsoft Access database [14]. Thus, structured information of every data item (as item name, datatype, measuring unit, min/max value, mapping to code lists, whether or not an item is mandatory) is available.

Thirteen forms were retrieved, which represent the complete set of CP which are obliged to be filled out by every German health care facility that provides CP. Table 1 lists procedure names and their associated diseases.

Table 1- PCI = Percutaneous coronary intervention, Tx = Transplant, ICD = Implantable Cardioverter Defibrillator

Procedure	Treated Main Diseases
Coronary angiography, PCI Coronary Surgery	Heart failure, Heart attack/Myocardial infarction, Coronary Heart Disease, Arterial Hypertension
Pacemaker Implantation Pacemaker Replacement Pacemaker Revision/Expl. ICD Implantation ICD Replacement ICD Revision/Expl.	Cardiac arrhythmias, Diseases affecting Heart's electrical conduction system
Carotid Revascularization	Cerebrovascular accidents / Strokes, Arteriosclerotic Diseases
Heart Transplant, Cardiac assistance Heart Transplant Follow-Up Heart+Lung Tx Heart+Lung Tx Follow-Up	Heart failure, Pulmonary hypertension, Cystic fibrosis, Congenital heart and lung affections

Form conversion and semantic enrichment

A converter was implemented to convert the original forms into ODM study forms according to the current ODM specification 1.3.2. Some of the original forms consist of sub-forms (e.g., QA form for Heart Transplant and Cardiac assistance consists of a "Follow Up"-, "Basic documentation"- and a "Procedure details" part). For conversion, a single sub-form is represented by one ODM-Form. Sub-forms belonging to one form share the same title prefix.

Altogether, the 13 original forms represent 24 forms including sub-forms.

A manual review of all original forms was carried out by three medical experts, including one physician with certified English proficiency (IELTS Band 7.5) to first translate German into English item names and then apply semantic coding using the UMLS Metathesaurus (version 2014AB) based on consensus decision.

Due to variations in concept granularity and some existing concept duplicates within UMLS that cause ambiguities when mapping medical terms into UMLS codes, we make use of previously published coding principles for pre-coordinated and post-coordinated concept codes [15]. Thus, form data items are assigned to UMLS codes with medical proficiency and previously used codes will be reused wherever possible. Data items whose values can be directly inferred from previous data items within the same form will not be coded. For example, the items "Year of Implantation" and "Year of Implantation is unknown" will be coded only once.

It has to be noted, that only the concept domain was regarded when mapping data items to medical concepts but not the value domain. Therefore, existing list items of a data item will not be taken into account for translation and semantic coding.

After having assigned UMLS codes, the medical context of each data item is defined language-independently. For many medical concepts explicit language translations are already available within UMLS [16]. The explicit translated language expression of a data item is defined by a "TranslatedText" element within the item definition according to ODM standard.

UMLS coverage analysis

During the process of semantic coding, all medical concepts that cannot be mapped with sufficient clinical specificity (according to coding principles, [15]) will be collected. These concepts will be marked with internal codes for identification.

Frequency Analysis of medical concepts

To provide a list of common data items, overall frequency of medical concepts that represent all data items will be calculated by counting same UMLS codes. Cumulative frequency analysis will illustrate cumulative coverage of most common concepts among the complete set of all concept occurrences within the acquired QA forms.

Clinical categories of most common concepts will be manually identified to represent the most common concepts within a hierarchical heat map tree based on manual expert review.

Thus, clinical categories are represented by tree nodes, which are based on hierarchical relations based on previous work [15] to cluster most common concepts in clinical trials.

Form sharing

All QA forms with semantic UMLS annotations will be uploaded to the forms repository [11] with open access for all registered users (registration is free).

The repository will provide form visualization and download, user-ratings, user comments, form-edition and form-versioning.

Results

Form conversion and UMLS coverage

Based on 13 original QA forms, 24 ODM forms have been generated with semantic codes for every data item wherever UMLS codes are available. The resulting 24 forms contain

1011 data items referring to 796 medical concepts of which 361 are unique.

Among those 796 medical concepts, 702 could be coded via UMLS codes (Concepts with missing codes: 94, Coverage 88%). The 94 medical concepts with missing UMLS-codes were semantically annotated with internal identifiers to count them for the frequency analysis of all concepts. Table 2 represents an extract of 5 concepts we deemed critically important, which are not defined by UMLS.

The full list of concepts is available in the supplement file: Coverage.xlsx.

Table 2- Critically important medical concepts that occur in QA forms, which are not covered by UMLS. PCI = Percutaneous coronary intervention

Concept Name	QA form(s)
1. Applied Dose Area Product (X-Ray exposure)	PCI, Coronary Surgery, ICD/Pacemaker Procedures, Heart Transplant, Cardiac assistance
2. Quality of transplanted organ at time of harvesting / transplantation	Heart/Heart-Lung Transplant
3. Door-to-Balloon Time in myocardial infarction	PCI
4. Lung Allocation Score	Heart-Lung Transplant
5. Multilevel lesions of carotid artery	Carotid Revascularization

Frequency Analysis of coded medical concepts

Tables 3 and 4 provide a top five and top ten extract of the most frequent concepts for demographic/administrative and clinical concepts, respectively. Both tables present for each concept its respective UMLS code (CUI) and relative concept frequency (RCF), which is the ratio of the absolute concept frequency of that concept to the number of all concepts occurring in the QA forms. For example, the concept "Date of Birth" occurred 15 times, since the total number of concept occurrences in all forms is 796, RCF=1,89%.

The clinical concept "Procedure code" has the highest RCF (3.89%), since all forms focus on cardiovascular procedures and some forms require more than once data items, which are conceptually related to the procedure code.

For the full list of concepts and their UMLS codes and absolute frequencies, see supplement file: FrequencyAnalysis.xlsx.

Table 3– Most frequent demographic/administrative concepts CUI: Concept unique identifier, RCF= Relative concept frequency

Concept Name	CUI	RCF (%)
1. Date of Birth	C0421451	1,89
2. Medical specialty of health care facility	C0037778	1,89
3. Gender	C0079399	1,63
4. Facility section identifier	C1547540	1,63
5. Zip code of discharge	C1521842	1,63

Table 4– Most frequent clinical concepts

Concept Name	CUI	RCF (%)
1. Procedure code	C1550373	3,89
2. R wave height	C0429049	1,89
3. (Discharge/Admission) Diagnosis	C0011900	1,76
5. Manufacturer Name (of medical device)	C0947322	1,50
6. Reason for Patient Discharge	C3164834	1,38
7. Number of times, planned procedure has been applied before (procedural record)	C2114712	1,13
8. ASA classification	C1531480	1,13
9. Procedure duration	C1442476	1,00
10. Applied Dose Area Product (X-Ray)	-Not available-	0.88

Figure 1 illustrates the cumulative coverage of all 361 unique concepts starting with the most frequent concept "Procedure code" (rank 1, frequency = 31) on the left hand side of the graph, followed by the remaining frequency-ordered concepts.

Blue circles indicate slope changes of the graph due to frequency reduction. The red circle represents the 112th most frequent concept, which has an absolute frequency = 2. All other concepts on the remaining right side of the graph share an absolute frequency = 1. Thus, it can be seen that by only using a third of all unique concepts (112/361), nearly 70% of all concepts occurrences in the QA-forms can be covered.

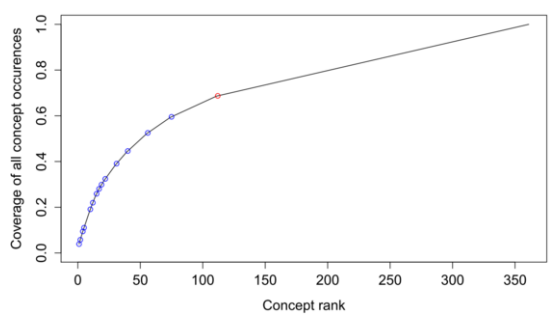

Figure 1– Cumulative frequencies, starting left with most frequent concept 'Procedure code' (rank =1, frequency= 31), blue circles indicate slope reductions, red circle marks concept rank 112, after which concept frequency = 1

Figure 2 (larger image available in the supplement) shows the category tree depicting clinical categories and subcategories fitting these 112 most frequent medical concepts. The color of a node indicates the number of concept occurrences within the QA forms that fall into the category represented by that node, similar to a heat map. Every category is annotated with a count number in parenthesis, which states the exact number of times medical concepts from the QA-forms fall into that category. Note that the count number of a parent's node doesn't need to be the sum of its child nodes' count numbers, since the parent node can contain concepts, which cannot be assigned to any of its child nodes.

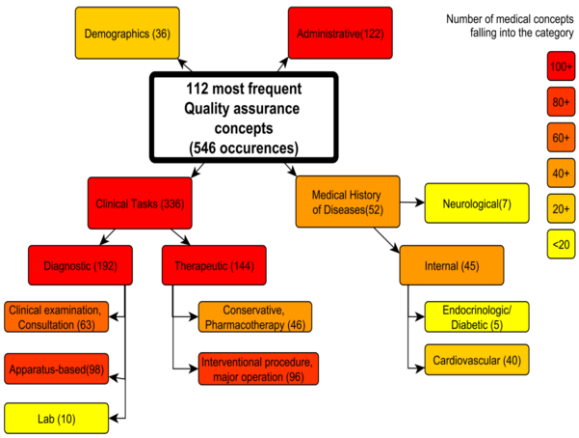

Figure 2– Categorical Heat Map Tree categorizing all 546 concept occurrences for concepts that have at least a frequency = 2. Refer to the text section for detailed description.

Medical categories as Diagnostic/Therapeutic processes and administrative processes encompass the most frequent medical concept occurrences for documentation of QA forms. Compared to our previous work [15] to cluster most common concepts for clinical trials the main category "Administrative" was used instead of "Trial/Research-specific concepts" to represent administrative patient-related QA data items like "Health care facility identifier" or "Zip code of discharge".

"Neurological diseases" is a further category next to "Internal medicine diseases", which contains some of the medical concepts (n=7) in the QA forms, since neurovascular accidents play an import role with people receiving cardiovascular procedures.

For the full list showing which concept was mapped to which category, refer to the supplement file: FrequencyAnalysis.xlsx.

Form sharing

All ODM forms are accessible on the form portal [11]. A search function for retrieving the forms presented in table 1 is provided. The exact names of form titles are given in the supplement file: Form-Names.xlsx. Forms can be downloaded as native ODM files and/or visualized on the website.

Figure 3 shows an extract of a detailed view on the item group "Operation" from the QA Form "Pacemaker replacement" containing the data items "Operation date", "Procedure codes" and "Procedure Duration" on the form portal.

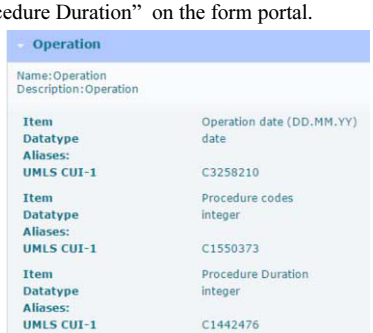

Figure 3– Detailed view of item group "Operation" on the form repository for the QA form "Pacemaker replacement" showing item names and semantic annotations.

Discussion

Conversion and Translation of Forms

Conversions between different formats are associated with a certain degree of loss of information. Since format conversion was applied from one structured format into another standardized structured (ODM) format this process could be implemented automatically. ODM at the current specification 1.3.2 provides the full amount of item structuring and item definition features to carry out the conversion without any losses of content relevant to medical documentation (e.g., layout-specific information or internal abbreviations as additional information was ignored).

UMLS coding and UMLS coverage

The analyzed QA forms are based on obligatory QA implementation in German hospitals since the year 2000 and established by AQUA [13] (commissioned by the German Federal Joint Committee) as a long-term consensus-driven result by medical specialists (doctors, nurses, health scientists, pharmacists, economists, statisticians, IT specialists etc.) [3, 4, 13]. Hence, data items of those forms have an evidential basis for medical significance in routine documentation to assess, maintain and improve medical quality for medical treatment.

Therefore, our results regarding medical concepts that represent data items of the QA forms and are not defined by UMLS indicate significant definition gaps. Even though most of the concepts occurrences could be covered, 12% remain undefined and are critically important to be incorporated into UMLS or other large medical vocabularies to make those concepts amenable for unambiguous identification, which is an important prerequisite for data harmonization and interoperability of medical data items.

Medical Concepts and Form Data Items

Calculated frequencies and established clustering of concepts are based on the mapping of all data items from the QA forms into medical concepts. It has to be noted that medical concepts represent the concept domain of a data item and not necessarily further information as value-domain-specific information or temporal information.

If the user is interested in which items are linked to concept codes our published form files can be searched for a given UMLS code, which is defined within a data item definition element. Furthermore a data item definition element contains information on measurement units, min and max values wherever this information was given in the original forms.

Limitations

Expert-based manual coding of data items is a time-consuming process, application of our methods on a larger set of form data items leads to an increase of coding efforts linear to the size of the item set. Carrying out multiple manual coding by different coders is possible, however it has to be noted, that UMLS is not a classification, it is a meta-vocabulary with some concept duplicates and varying concept granularities leading to potentially different code mappings among different coders. Since we apply our methods on previously published coding principles [15] and a very limited set of different medical experts as coders with consensus-based code mappings, identification of different medical concepts is based on medical expert knowledge and the mentioned UMLS coding issues could be counteracted.

Translation from German into English items, which is the prerequisite for mapping into language-independent UMLS codes, was limited to only one medical expert as a translator

with certified IELTS-English Proficiency (Band 7.5). A certified medical translator was not involved in this work. However, since the work is based on the translation of data items with a limited sequence of words and translation is carried out by a medical expert, content and context of medical translation should not have produced misleading results. Additionally, a platform is provided for international discussion and reuse enabling registered user to suggest editions of the currently available forms. With the provided web-portal infrastructure and an integrated web-based ODM form editor, changes of translation and new languages additions (including code list items) are supported without losing the content structure. For illustration purposes, see [12].

Conclusion

The work provides the first E-forms for quality assurance for cardiovascular procedures containing language-independent data items with semantic codes. A platform is provided for open-access to enable world-wide reuse and versioning.

Frequency analysis and clusters of medical concepts that represent data items provide a set of conceptual common data elements. It could be shown, that by only using around 30% of all unique medical concepts, nearly 70% of all concept occurrences could be covered when only focusing on the most frequent concepts. Therefore, these most frequent concepts should be given special consideration when forms relevant to cardiovascular QA documentation are being established.

UMLS-coverage analysis indicates concept coverage of nearly 90% with few but critically important concept definition gaps. A UMLS update of the presented concepts is therefore strongly recommended.

Abstract

The rapid migration of health care from the institution to the home presents a plethora of consumer health technology options.. The fit of these technologies to the users' actual task performance and environment remains to be explored. In the vizHOME study, we set out to conduct in-depth analyses of health information management tasks conducted by individuals residing in 20 homes in the Midwestern United States who self-reported with diabetes. This paper will explore early results from five of the 13 assessments we have performed to-date. Early observations are described and implications for informatics are posited.

Keywords:

Self-management; Personal health technologies; Chronic illness; Task analysis; Human factors.

Introduction

The rapid migration of health care from the institution to the home presents a plethora of consumer health technology options. However, few of these are developed with an understanding of chronically ill individuals' health information needs, their abilities to meet these needs and how they use this information in managing their health and health care. Importantly, the place within which a person conducts specific tasks is rarely documented or explored. Yet there is growing evidence that context shapes health information management behaviors [1]. There is also growing evidence that better understanding of these self-management behaviors might lead to both clarification of the health information management challenges faced in the home and improved design of the technologies intended to be used there [2]. For example, Valdez et al. [3] propose a patient work model which involves attending to "the embeddedness of patients' health management in larger processes and contexts and prioritizing patients' perspectives on illness management".

The vizHOME project is designed to systematically determine how household context shapes self-health management including personal health information management (PHIM). PHIM encompasses a suite of cognitive and behavioral tasks that people undertake to accomplish their health goals. These include monitoring health states, recording symptoms, communicating with clinicians, as well as making sense of discharge summaries, health-related web sites and clinician-provided handouts. Often people undertake PHIM at home, and the home's physical features such as storage adequacy, lighting, privacy, and proximity of health information management tools influence the person's ability to recognize and complete the cognitive and behavioral tasks. Knowledge of which features of the household context shape PHIM can be used to better design technologies for PHIM. Our long-term goal is to improve individuals' self-management and health outcomes by accelerating the design and adoption of PHIM-supporting computer technologies that explicitly take into consideration features of the home context.

A key element of this study is in-depth assessment of the individual's self-management behaviors or self-care task performance as well as the devices they use in order to better understand the informatics issues in the design of tools and technologies used for these tasks. The focus of this paper is on the first phase of the vizHOME study, specifically on the exploration and documentation of the individual's performance of self-management tasks including such things as medication management and use of a monitoring device. A LiDAR scanner is used to capture the entire interior of participants' homes; these images are subsequently rendered for viewing the context of the homes in a 3D CAVE. A detailed discussion of the technology and processes used will be reported elsewhere.

The target population for this study is adults who report having been diagnosed with diabetes. Estimated to double globally from 171 million people in 2000 to 366 million people by 2030, diabetes is expanding both the amount of personal health technology many patients use regularly [4] and the personal health information management (PHIM) demands placed upon them. Individuals diagnosed with diabetes have a large burden for self-management, including self-monitoring of blood glucose, observing for complications, managing an array of ingestible and injectable medications and adhering to instructions from multiple health care providers. Each of these tasks have significant information management demands (recognition, recording, communicating, interpreting) and many technologies are being developed to assist patients to manage these tasks. Situating this first investigation of how household context influences PHIM in the homes of individuals with diabetes is valuable because much of the management of this disease occurs in the home, interspersed within their daily lives.

The task assessment is guided by SEIPS, the Systems Engineering Initiative for Patient Safety model [5]. This model posits that the work system (in this case, a *patient* work system), a structural concept, influences how processes occur, which in turn shape outcomes. The health care work system is defined as the integration of a person attempting one or more tasks using a given suite of tools and technologies in a specific physical environment influenced by the policies and procedures of a specific organization. We translate this to the home context, in which the person is the lay individual who is attempting self-management tasks for self or others using the available supplies, computer tools and resources in the informal household environment following the culture, family practices and other influences on intimate life at home. In this project we will focus on the work system in the home, with particular attention to aspects of the physical environment and personal health information management tasks.

Methods

Institutional Review Board approval was obtained for both project development activities as well as for the in home assessments from the University of Wisconsin-Madison Health Sciences IRB.

Sample

We partnered with The Survey of the Health of Wisconsin (SHOW) project to identify participants for this home task assessment. The SHOW has been conducting annual surveys since 2008, and at the beginning of 2012 had a growing cohort of over 2,500 Wisconsin adults. Eligible participants are men or women between 21and 74 years old who self-report being told that they have diabetes mellitus. They must be cognitively intact and able to read and write English. To enable in-home conduct of the interview, participants must live within a 100-mile radius of the project team's home institution in Central/South Central Wisconsin. Target enrollment is 20 participants for this home assessment phase of the study. We targeted five participants who live in one of each of the following home types: detached, semi-detached, multi-unit and mobile home. Twelve home assessments have been completed to date.

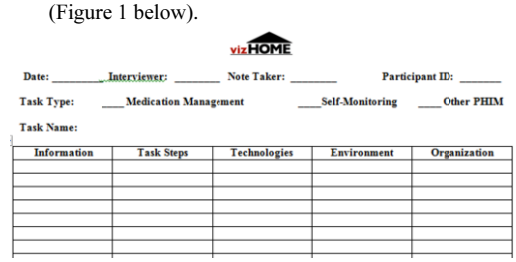
Data Collection Procedures

Interviews were conducted by study team members with a background in human factors engineering or nursing. A second person whose role is to take detailed notes is usually present as well. With participants' agreement, interviews were also audio-recorded for quality assurance purposes. After providing informed consent, participants respond to questions about their health concerns and self-monitoring and self-management practices. Interviews were conducted iteratively over three home visits using researcher-developed semi-structured interview guides based on the SEIPS Model. They were usually conducted solely with the participant unless the participant requested another household member be involved. Therefore, the participant is the primary source of information about the task performance. When the participant identified another household member as a better source of information about a specific process, that member was either included in the interview process or consulted at another time. A schematic map was created during a walk-through of the home during the first visit. This map served as a model that enabled us to anchor tasks or specific task steps to specific locations in the home. The participant was asked to identify key areas during the initial walkthrough and subsequent visits, and the interviewer requested the participant demonstrate specific tasks in the locations where they were actually performed.

The first visit most often included the interviewer and note taker. Subsequent visits (two and three, four if needed) involved both the interviewing team and the scanning team. Because people could not be in the area where scans were being done, the interviewers and scanners coordinated plans and activities.

The interviews and the intervening analysis proceeded as follows:

- Interview 1: introduction to the study and study team; obtain informed consent; questions about health and health information management tools, *health concerns inventory and health task inventory*.
- Intervening Analysis: *selection of three tasks for follow-up in Interview 2*. Individually and in pairs team members reviewed interview notes and audio recoding to discern three information-intensive tasks that are important to the individual. Responses were topically organized into three task types: medication management, self-monitoring and management of health information, noting specific indicators of all elements of the work system (information, task steps, tools and technology, environment and organization). Tasks were refined in a way to guide the scope of the in-depth exploration.
- Interview 2: *Generating rich descriptions of the selected three tasks.* One interviewer and the note taker returned to the home to undertake an in-depth exploration of each of the thre tasks. As the interview focused on the information intensive tasks undertaken by the participant, a grid was used to facilitate notetaking with a focus on information and the remaining four elments of the SEIPS model (Figure 1 below).



vizHOME

Date: _____ Interviewer: _____ Note Taker: _____ Participant ID: _____

Task Type: ___Medication Management ___Self-Monitoring ___Other PHIM

Task Name:

Information	Task Steps	Technologies	Environment	Organization

Figure 1 - Task Analysis Grid

- Intervening Analysis: Between interviews two and three, the interview team reflected on participant responses and created a transcription of the modified SEIPS grid as described in detail in the Analysis section below.
- Interview 3: *Respondent confirmation.* This interview was conducted to validate the interviewer's analysis and understanding of the task information and to obtain clarification when needed.
- Summative Analysis: Following the third interview, synthesis documents were created. These summary documents include task process summaries, a home persona, and an integrative case summary that addresses the tasks performed in the context of the home and technologies used.

Data for a cumulative visit log and background information was collected over the series of visits. Data included date and time of visits, location of the home (urban, suburban or rural), length of time in home, any perceptual or mobility limitations experienced by the key respondent, a list of others living in the home and presence of pets. Using a visual analog-type scale, the interviewer and note taker also rated the amount of clutter in the home. Differences in the two clutter ratings were discussed and resolved either by agreement or interpolation between scores.

Analysis

One task grid was created for each of the three tasks reported by the participant from each household. These were stored in computer files as pdf documents that could be annotated by team members.

The actual analysis of the raw data to create task grids for each task and each individual proceeded as follows.

Following the second in-home visit, the detailed notes from each task analysis were used to create a Task Analysis Grid for each task. The intent of the Task Analysis Grid was to create an "instruction manual" for the task *as the participant re-*

ports performing it, including the information (content and strategies) used so that the task could be replicated independently by anyone reading the grid. Task steps were arranged sequentially in the order the participant reported (or was observed) executing them. Efforts were made to discern task steps sequentially during the interviews. When this was not possible the analysis process involved imposing a logical task order response denoting information used, task step performed, technology or tool used, environment (i.e. location in the home), and organization were separated into the appropriate columns within the modified SEIPS grid. The interviewer created the grids using his or her own the notes as well as those written by the note taker in order to minimize errors and personal bias. If inconsistencies were encountered, the two home visitors discussed these differences and if a consensus could not be reached the topic was revisited in the third in-home visit.

After the Task Analysis Grids were completed to the extent possible, missing elements (evident as holes in the grid) were highlighted and questions structured to address these gaps. This missing information, as well as any other questions that emerge when constructing the grids, were compiled into an interview guide for the third in-home visit for the purpose of confirmation and clarification.

At the end of each household assessment we have an electronic file that includes a profile of each home, data about the house itself, descriptions of the patient work system, and descriptions of context (text, still photos and drawings). The data analysis process applied the Health@Home model [6] to begin to characterize information management practices by purpose and location. Additional analysis focused on determining whether there were differences in how similar tasks are done in different households. Finally, we reviewed home maps and images to facilitate reconstructing task activities across space.

Other analyses that will be undertaken, but are not reported here include: data cleaning and verification, descriptive statistics on demographics, background health information and household environments, and task processes.

Results

The five participants described here were systematically selected as representative and presenting a range of behaviors related to each task. A profile of each participant is presented. The findings are organized by task: medication management, self-monitoring and information management.

Demographics

The five participants range in age from early 30s to early 70s. They are diverse in terms of racial and ethnic background. Two participants live alone, two live with a spouse and one lives with a spouse and pre-school children. One participant resides in semi-detached home, two in multi-unit and two in a detached home, thus they represent four of the five home types.

Participant Profiles

Participant A lives alone in a one-bedroom apartment in an urban area. She has several chronic illnesses in addition to diabetes. She is solely responsible for her health and healthcare. She has a primary care provider, a diabetes specialist and a case manager.

Participant B is retired and lives with his wife in a semi-detached suburban home. In addition to having type 2 diabetes, he has several chronic health conditions, most related to his heart. He regularly (one to four times per year) sees a primary care provider, a cardiologist, an electrocardiologist and an endocrinologist.

Participant C has insulin dependent diabetes. He lives with his wife in a detached urban home and is employed full time. He has hypertension and elevated cholesterol.

Participant D is a retired woman who lives alone in a two-bedroom apartment in an urban area. She self-reports as obese and has elevated cholesterol, chronic back and hip pain.

Participant E is a married man who lives with his wife and children in a detached suburban home. He works full-time outside of the home. He has several chronic conditions including insulin dependent diabetes, hypertension and elevated chrolesterol.

Task: Medication Management

Participant A*:* In addition to the prescribed 12 pills taken daily, Participant A uses eye drops at least daily, takes *as-needed* medications for pain and airway management and self-administers a weekly injection. She uses a weekly pill organizer to manage her twice-daily medications. She describes her medication taking as a routine for which she does not require cues. Participant A keeps her pill organizer on a bedside table and an injectable is stored in the refrigerator. She "rarely" forgets to take prescribed doses, but knows what to do when she does forget. Her source of medication information is primarily her primary health care provider. She also receives drug information from the pharmacy which she carefully reads and then immediately discards.

Participant B takes nine medications daily, divided between the morning, dinner time and bedtime. He takes his medications from the bottles in which they are dispensed. All but one medication bottle are kept on the bureau in his bedroom; each morning he counts out the day's pills and lays them on the bureau. At some point during the day he moves the pills to be taken in the evening into the kitchen and puts them on the counter. The single medication taken with the evening meal is kept on the dining table for convenience and to serve as a reminder to take it. He is meticulous in following his prescribed medication regimen and almost never forgets a dose. He maintains a hand-written list of current medications and revises it whenever changes occur. He keeps pharmacy inserts for current medications organized in a folder in his bedroom and states he would refer to them if he had any questions about his medications.

Participant C takes five different medications daily, including insulin in the morning and evening. Each day he takes his morning pills out of bottles and puts them in his pocket to take at work. He also takes a bottle of insulin and a syringe to work for his morning dose. He takes his evening insulin and oral meds when he gets home from work. His medications are stored in a bathroom cabinet that he shares with his wife. He checks the bottle label each time he takes a dose to ensure he is taking the right medication. He "sometimes" forgets to take medications to work with him; when this happens he resumes regular dosing the next day. He relies on his pharmacist to relate relevant medication information and discards informational inserts when he receives them.

Participant D takes 14 pills per day for several chronic conditions including "borderline" diabetes, hypertension, hypercholesterolemia, heart disease and arthritis. Her health care is delivered through a community-based clinic that includes a pharmacy, a senior center and social services as well. A pill organizer is filled by the clinic pharmacy and delivered to her on a weekly basis due to difficulty in maintaining correct dosing. She keeps this organizer on a

table in her bedroom. If she is going out for the day or plans to stay in her living room, she transfers single doses into a small pillbox to keep with her. Routines around waking up and retiring for the night serve as reminders to take her medications at those times; she uses specific shows on television as cues to taking daytime meds. She does not receive pharmacy inserts with her medications; the organizer has labels with the names of the medications it contains on the bottom. She stated that she "would not understand the detailed information anyway". She reports that she sometimes forgets to take a dose and will take it when she remembers "if it isn't too late" or will just skip it.

Participant E has oral medications that he takes in the morning and evening. He also takes scheduled doses of mixed insulin in the morning and before his evening meal. In addition, he has "sliding scale" regular insulin prescribed four times per day, but he rarely checks his blood glucose more than one to two times per day because he is "busy". His oral medications are stored in cabinet in the master bathroom; pill bottles are organized on a shelf from right to left according to time taken. He takes the morning oral medications, one at a time, in the bathroom. The insulin pens are stored with his glucometer in a drawer in the kitchen. He stands at the kitchen counter above the drawer to use his glucometer and inject the insulin. He might read medication information when a new med is started otherwise discards information when he receives it.

Task: Self-monitoring

Three of the five participants described above received a glucometer to monitor their blood sugar at varying frequencies from daily to several times per day. One participant adhered to the prescribed frequency while others used the glucometer 1-3 times per day less than expected. Some occasionally manually logged the glucometer readings, usually to share with their health care provider. While all had a glucometer with a history feature, none reviewed readings in the history. One participant did sync the glucometer to his smart phone and sometimes reviewed readings in it. All reported knowing what range their readings should be in and what to do if the readings were not in range.

Table 1 - Self-monitoring

Participant	A	B	C	D	E
Glucometer Prescribed	yes	no	yes	no	yes
Frequency	1+	*heart	2-3		1-2
Storage Location	bed-room	phone	back-pack		kitchen
Use Location	bed	bed-room	work, home		kitchen
Records Results	some	digital	no		no
Takes to MD appts	yes paper	dials in	synchs to phone		yes glu-cometer

Remarkably, they attributed such information to learning from their health care providers and all was committed to memory. Table 1 summarizes the particicpant's self-monitoring of blood glucose level. Note that Participant B did not have a glucometer, but did regularly monitor his cardiac status. He used telemonitoring to provide data to his cardiologist and has done so since he had an implanted defibrillator inserted years ago.

Task: Information Management

Participants reported a variety of policies and approaches to information management. For some, information was defined as a reminder or cue to begin a task; for others it was in the form of care instructions conveyed by a health care provider.

Table 2 - Information Management

Partici-pant	A	B	C	D	E
Format	paper	paper	paper	paper	paper
Seeks	no	yes	no	no	yes
Reads	yes	yes	about device	occa-sionally	scans
Shares	no	w/wife	no	no	no
Disposi-tion	keeps new	keeps new	discards	dis-cards	dis-cards
Storage Location	bed-room basket	bed-room bureau	phone, if any	n/a	n/a

For still others it was paper-based and included self-care recommendations, manual-type literature, general health and disease-oriented publications or pharmacy-inserts. Remarkably, most reported having a personal health record (PHR) but regardless of their information seeking and management behaviors, none accessed the PHR. A summary of select information management strategies is contained in Table 2.

We noted a single commonality across tasks and participants – each had a stable set of strategies which they applied to the PHIM tasks they performed. In spite of this, we noted a high level of unique approaches in terms of the behaviors within tasks of similar types. In addition it was often difficult to determine discrete beginnings and ends of the task. Finally because all tasks are influenced by the fit within the person's life, there is a lack of a "gold standard" for performance.

Similarity/Difference Analysis

Generating design recommendations requires first determining the extent of similarities across people within tasks. Previous methods [7] were not applicable to this analysis. We undertook the following analyses in order to detect similarities and differences within tasks and across participants.

All tasks were first grouped by high-level similarity. For example, every participant taking daily medications was documented. Many participants self-monitored and treated blood sugar levels; this was also documented. There were several other groups of tasks that were performed by smaller numbers of participants. A group was defined as at least two participants performed a given task.

Two analyses were conducted on the data from the Task Analysis Grids: 1) location analysis and 2) task step similarity analysis. For each analysis a color-based coding key was generated. For the location analysis each different type of room or location where task steps occurred was represented by a different color (e.g. kitchen, bedroom, living room, closet, etc.). The coding key was limited to areas where task steps actually occurred in the study; it was not an exhaustive list of all possible locations in the homes that could be used. Multiples of the same type of room were documented when appropriate (e.g. master bedroom vs. other bedroom). For the task step similarity analysis a similar color-based coding key was created with high-level designations for the type of task step recorded (e.g. administering medication, documenting, assessing personal status, etc). This list was also limited to observed behaviors and not exhaustive of all possible behaviors. Selected columns of the Task Analysis Grids (i.e. Information, Task Steps and

Environment) for the tasks in each group were arranged side by side in a spreadsheet to allow for comparison. The two analyses were performed separately on transcribed copies of the grouped tasks.

In the location analysis the cells in the Environment columns of the Task Analysis Grids were coded by the location in the home where each task step occurred. When a task step involved transition between different locations or when it might be done in different locations the cell was marked with both colors.

In the task step similarity analysis the cells in the Task Step columns were coded by the type of task step that occurred. In similar fashion to the location analysis, when a task step spanned more than one type of behavior the cell was marked with multiple colors. In this analysis, some cells were left uncoded if the behaviors were not sufficiently close to one of the coded types or if they were redundant with other task steps. As identified earlier, when analyses were conducted at a relatively granular level, more differences than similarities were detected.

Discussion

The design and implementation of supportive technologies continues to proliferate. We learned from these five participants that while the tools may perform satisfactorily in usability assessment, they may not meet the needs of many users. An example is the growth and increased availability of personal health portals. Although many of the vizHOME participants had access to some type of personal health record (PHR), few if any used it. Although the scope of the study does not include exploration of non-use, we anecdotally learned there may be several underlying reasons related to access (technology), usefulness, or demand.

Another reported reason for non-use of tools aimed at supporting self-care is the level of the content. One participant reported she did not read or keep medication information from the pharmacy because it was "like reading a foreign language". Given this admission, one should consider the importance of providing information that consumers can understand and apply in self-monitoring and self-management. Translating such information into a vernacular that is readily understood by the consumer may be needed.

We also found that most of the vizHOME participants had access to a computer or had some type of internet access. Despite the capacity, they tended to not use not use electronic methods for health information access, interpretation or storage. With the increase in computer generated cues such as pushing information or reminding patients about health care appointments, consideration should be given to translating such cues to commonly used household items such as a calendar.

Conclusions

Health information management task performance demonstrated more differences than similarities than we originally anticipated. These differences present additional challenges to those who design tools and technologies for self-care. Indepth study of people as they manage their illness or health at home will continue; we expect that this will generate a better understanding as well as provide guidance for the design of self-care technologies.

The Use of Applications in Distance Education Specialization Course as a Support Tool for Students Living in Remote Areas Without Internet

Ana Emília F. Oliveira [a], Rômulo M. França [a], Eurides F. Castro Júnior [a], Deborah C. L. Baesse [a], Mariana F. L. Maia [a], Elza B. Ferreira [a]

[a] Open University of Brazilian National Health System (UNA-SUS), Brazil

Abstract

The world is experiencing the popularization of mobile devices. This was made possible by the increasing technological advances and the advent of the Internet as a communication and information tool. These facts demonstrate that the development of applications compatible with such devices is an effective way to provide content to diverse audiences. In the educational field, these devices can be seen as technological support artifacts for distance education, serving as strategy for continuous and permanent education for health professionals. The Open University of Brazilian National Health System (UNA-SUS) offers distance learning courses, including specializating on free access. In order to increase the public reach, UNA-SUS developed mobile applications as supporting material for students. These applications can be accessed in offline mode, increasing the accessibility and therefore, improving the efficiency of the material. The 28 applications developed with responsive online books format currently reached the milestone of over 6,000 downloads. This number shows the positive acceptance of the format used, accentuated by the ease of having material downloaded from the device, not requiring the user to be connected to access content.

Keywords:

Mobile Applications; Distance Education; Mobile Device; Permanent Education in Health.

Introduction

The combination of the Internet and mobile devices, such as smartphones and tablets, tools for communicating and spreading information has been on the rise. The popularization of mobile devices has been considered by many as the technological revolution with the greatest impact in recent times. The impact is not only because it allows more convenience in accessing information and communication, but also due to the characterisctics of such devices considered pocket computers, which allows access to millions of applications. According to the IDC (International Data Corporation) in 2012 [1], more than 40 billion apps have been downloaded on smartphones, and it is predicted that this number will reach 300 billion in 2016 [2,3]. Therefore, it is clear that developing applications whose format is compatible with mobile devices has become an effective way to provide certain content to specific target-audiences [4].

Information technology (IT) applied to education has transformed school environment and generated innovations in learning. The trend in teaching-learning models is to try to overcome time and space boundaries and reach students regardless of where they are or when they are available. Although this claim has not been fully achieved yet, distance education has occupied a significant space among the pedagogical tools used [5].

Distance education (DE) is a technological two-way communication system that may be considered as an alternative to the traditional classroom teacher-student interaction model and allows learning without the need of those involved in the process to be present in the same location interacting at the same time [5,6]. Therefore, despite the physical distance between teachers and students, distance education makes use of ways and technologies in order not to compromise the process of transmission of knowledge. In this case, mobile devices can be seen as a supportive technological artifact, so that distance education reaches the virtual integration of learning vectors.

If we pay attention to health professionals and to the difficulties faced by them, we realize that, more than any other, they need to constantly update their technical, technological and social skills, while respecting ethical principles governing their conduct. For these workers, distance education would be a strategy for continuous and permanent education, given the numerous technological advances and pedagogical innovations in education [7].

UNA-SUS is a project from the Brazilian Ministry of Health developed in partnership with the Work and Health Management Secretariat - SGTES in order to offer Brazilian National Health System (SUS) workers democratic, flexible and quality education, respecting employee's working time and their place of residence. Seeking to improve the qualifications of health workers through Distance Education, the Open University of Brazilian National Health System (UNA-SUS), in partnership with the Federal University of Maranhão (UFMA), offers specialization, training and extension courses with free access, with the goal of providing training in strategic areas of health care service.

The courses offered by UNA-SUS reach a target-audience with the following characteristics: residents living in of remote areas limited Internet access, lacking of time to study and having intense days of work. These factors would hardly allow them to attend traditional face-to-face education. If we merge the increasing demand for distance learning courses to the popularization of mobile communication devices, we have the ideal solution for the development of innovative teaching methods. Following this reasoning, UNA-SUS/UFMA is a pioneer within Brazil in developing applications for mobile devices as background material for students. These applications have technological capabilities allowing offline mode (no Internet access), increasing the material's accessibility and efficiency.

Materials and Methods

Territorial Reality

UNA-SUS/UFMA is located in the state of Maranhão, which has 217 municipalities, and a current population estimated at 6,850,884 inhabitants [8]. Since Internet access is limited in areas far away from metropolitan region, the state's vast territorial field represents a challenge for the attainment of distance education initiatives such as UNA-SUS/UFMA. Figures of 2010 Census show that Maranhão is the last in the list of federal units with computers connected to the Internet, with the capital São Luís having the highest access rate [9]. Moreover, according to a recent Teleco survey – the biggest information portal in Brazil's telecommunications sector – out of the 217 municipalities of Maranhão, 39% do not have 3G Internet coverage [10]. However, it is exactly in these regions where the most urgent demands for training are located, especially for health professionals, the very target-audience of UNA-SUS/UFMA.

Distance education has been considered an important tool by the Brazilian National Policy of Permanent Education in Health and has been well accepted by its participants. However the difficulties concerning the access to Internet have still been a limitation to the growth and success of these initiatives [11].

Theoretical Basis for Applications Development

According to research from Business Insider five years ago, much of Internet accesses from desktop computers. In 2013, 22% of the population owned a smartphone, an increase of approximately 1.3 million in the number of smartphones since 2009 [12].

Given the prevalence of smartphones with Internet access, distance learning must adapt its educational tools in order to reach those with mobile devices. Since it is not feasible to build specific websites or applications for each platform and device that a user can use, adjustments must be made so that applications work correctly in any variety of mobile equipments that one can use to access educational material [13].

The Responsive Web Design (RWD) was chosen as a solution that enables adaptation to user behavior and to the environment used to access the information. It also takes into account the platform, the resolution and screen orientation. Responsive Web Design includes techniques and technologies that are adjusted to make a single application run on a variety of devices in the most utility way possible [14].

Responsive Design aims to attend this kind of demand by fulfilling the following requirements [15]:

- Adapting layouts to different screen sizes;
- Resizing pictures according to screen resolution;
- Supplying images optimized for the aspect ratio of mobile devices;
- Simplying page elements to mobile versions;
- Hiding non-essential elements on smaller screens;
- Providing buttons and links with large clickable areas for mobile devices;
- Detection of mobile devices' specific features such as screen geolocation and orientation.

Besides Responsive Design's aspects, to obtain quality material capable of providing a motivational and pleasant educational experience, it is essential to develop it on pedagogical notions basis about educational interfaces that are favorable to learning and knowledge assimilation.

An attractive interface with appropriate interaction devices has a positive impact on the software's usability, acceptance and learning promotion capacity. Therefore, the software's design and its interface should be aligned with appropriate pedagogical principles, providing characteristics such as content and interaction presentation format up to the amount of information presented [16].

Hence, applications created and made available by UNA-SUS/UFMA are developed based on the learning objects concept, aimed at being integrated into different hardware platforms, including mobile devices, in addition to enabling access without the requeriment for Internet connection. The design of these learning objects prioritizes content, student interest and learning theories [17].

Learning objects are educational materials for pedagogical purposes that serve to support teaching-learning process. They are built in small groups or blocks with which learning content is structured. Their use is more efficient when they are cataloged on metadata and stored in a repository integrated to a learning management system, so that, in case of replacement or platform upgrade, there is no need for redesign [18].

Learning objects cataloguing offers other benefits beyond reusability, such as [17]:

- Accessibility: ability to access educational resources in a remote location and use them in many other places;
- Interoperability: possibility of using components developed in one location, with a set of tools or platforms, in other places with other tools and platforms;
- Durability: ability to continue using educational resources when their technology base changes without having them redesigned or reprogrammed.

Academic software from UNA-SUS/UFMA provide students with educational content for their courses in a digital book format, ensuring interactivity, a key aspect to learning process. Hypertexts and images, which meet visual adaptation criterias set by Cognitive Theory of Multimedia Learning, have become attractive and understandable to students and enabled the possibility of 'navigation' the way they want, respecting their time of learning [18].

Cognitive Theory of Multimedia Learning states that, once combined, multimedia narration and graphic images produce verbal and visual mental representations that integrate with prior knowledge to build new knowledge. This way, words and corresponding pictures must be close together, since they facilitate construction of related links between them [19]. Therefore, the use of images to illustrate concepts is essential in educational content.

Another important aspect to promote meaningful learning in a virtual environment is to design activities that reduce cognitive load, free memory capacity for deep cognitive processing during learning, increase students interest, and encourage them to use that freed memory for deep processing during learning. In others words, the interest can be stimulated by simply presenting the material in a visually appealing way, accompanied by text or animated and pleasant narration [20]. Therefore, a major concern of UNA-SUS/UFMA during the creation of its applications is to make adaptive images, so they do not suffer changes that could make them dysfunctional in the transmission of available content.

Educational Planning

Within the production of educational resources, UNA-SUS/UFMA provides content planning that will be used in its applications: defining all supporting materials to be used in the module and, later on, didactic planning of these modules. In the planning of supporting materials, definitions of all the tools that will be used in the module, such as videos, support texts and description of assessment activities, always trying to choose these materials carefully, and evaluating the possibility of their access in the application [21].

Didactic planning takes into account the course's or module's workload, target-audience and learning objectives. In the planning of each unit, learning objectives are defined, description of the discussed content is created, designing the presentiaton of the module and suggestions of learning evaluation are made. Based on this didactic planning, modules are built from the content and activities definition text to the process of Instructional Design.

For applications that work in offline mode, it is taken into account that the purpose of their construction is to facilitate access to course content developed by UNA-SUS/UFMA, especially for students who work in locations with limited access to Internet services. Therefore, the option for not providing online supporting materials and assessment learning activities is purposeful, so that didactic and modular planning is architected with the necessary adaptations for this technology [21].

Application Creation Process

The application development process took place with participation of two sectors of the institution: Institutional Design sector (ID) and Design and Information Technology Center (ITC), each one having a different responsibility in applications development. Institutional Design sector is responsible for developing all educational content, prepared by professors responsible for creating online content, which will be available to the student. The Design sector is responsible for developing the entire graphic part of online books such as icons, images and color palette. Finally, ITC has the responsibility of developing digital book in form of mobile applications and publish it in Virtual Learning Environment (VLE).

Applied Technology

Applications created by UNA-SUS/UFMA are developed in HTML5 (HyperText Markup Language 5) CSS3 (Cascading Style Sheets 3) and JavaScript. In addition, mobile versions of digital books are generated as an application for Android and iOS platforms, using Phonegap/Apache Cordova technology.

HTML5 is suitable for the development of responsive interfaces. It offers advantages that HTML4 and XHTML languages do not, such as the fact that most mobile devices have browsers that support HTML5 and CSS3. This type of approach in cross-platform development frameworks for mobile devices is intended to provide better user experience, with greater flexibility and media insertion possibilities [22].

In addition, applications developed in this language are optimized for smaller screens. The device's operating system has no control over their content or functionality, but developers can make changes at any time with immediate effect for users [22].

Application Presentation

All applications for mobile devices are available in both platforms of Google's store (Play Store) and Apple's store (App Store), and can be found through the search tool, using the words UNA-SUS UFMA (https://play.google.com/store/search?q=una-sus%20ufma). Currently UNA-SUS / UFMA has its whole application in English, and its content is dedicated to Postpartum Depression (https://play.google.com/store/apps/details?id=com.unasus.appdpp).

Currently, 28 modules were already developed and made available in the format of responsive online books by UNA-SUS/UFMA, enabling the mark of more than 6,000 downloads until this moment. This tells us that there is a positive acceptance of format used, accentuated by the ease of having the material downloaded from the device, not requiring users to be connected whenever they need to access content.

Figure 1 illustrates the presentation screen of the online book, visualized from both desktop and mobile device screens. All the elements of each page (navigation bar with arrows, navigation between pages, the tool to increase the font size) can be well accessed through the application, because the buttons were designed to be compatible to human finger size.

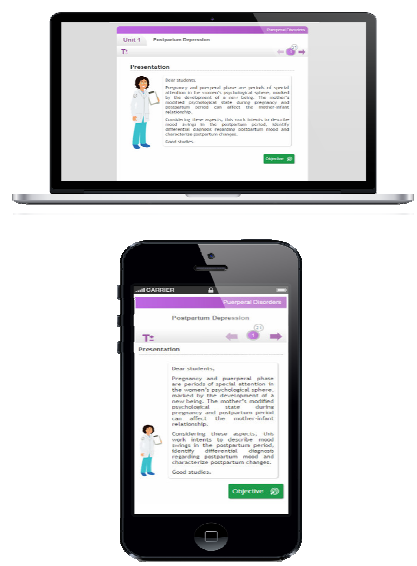

Figure 1 – Screen Presentation Mobile and Desktop

Figure 2 shows the contents view of a unit of digital book about Postpartum Depression (PPD) in the application.

By clicking on each gray button (Baby Blues, Postpartum Depression and Puerperal Psychosis) the text box below the woman's figure changes, providing detailed information concerning the gray button clicked on. This way, there is a space on the screen is saved, allowing a significant amount of content on a page without it being polluted with too much text, which would make the reading difficult and tiresome, especially on the small screens of mobile devices. All techniques used to build the applications are designed to make each online book page less visually polluted, while providing important informations on each topic, which means that there is no reduction in the content, but use of technological strategies for dynamic and smart use of the area in each page.

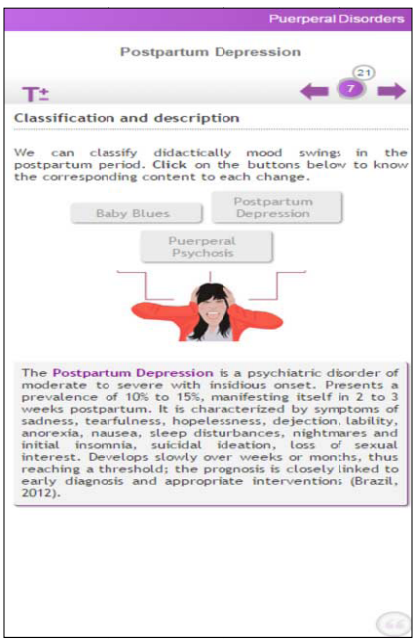

Figure 2 - Screen of a Content from a Digital Book in the App

Given the experience of UNA-SUS/UFMA in applications for mobile devices, some points can be highlighted as positive in the use of this material as a resource for students living in remote areas without Internet access, such as [21]:

Mobility, that refers to the fact students can load applications modules everywhere, since their mobile devices remain connected throughout the day due to its multiple features and possibitilies for locomotionincreases the mobility of the application. Ease of access is directly related to offline availability: students only need to install the application once on their device, in others words, only one Internet access is absolutely mandatory. From this, the application is available on your mobile device and can be accessed even without Internet connection. This attribute is one of the most relevant to UNA-SUS/UFMA, since most of its students live far away from the state's capital and have difficulties accessing Internet. Thus, studies are not interrupted if there are any connection problems: digital books' content is available at any time on students' device.

If there are updates for mobile application regarding new content or corrections, automatic updates are performed. In such cases, there is no need for students to intervene since this work is done by the web server of application's store. The cross-platform interoperability is characterized by the fact that digital books are developed once in HTML5 and adapted as open applications through PhoneGap. The specific implementation is not required for each mobile device platform (Android and iOS). Another positive and differential point regarding UNA-SUS/UFMA's applications can be found in the experience made available to the user. This is because content, images and animations and others features offered to students in the digital book of Virtual Learning Environment on their computer are available in the same way on the corresponding application for mobile devices. This means that students will not be harmed in relation to content or in any pedagogical sense for studying on screens with lower resolutions [21].

Conclusion

The popularization of mobile devices with Internet access has created an unique opportunity for Distance Learning, since it allows learning to happen anywhere, anytime, without relying on a physical connection line and with an equipment whose cost is lower than computers in general.

In this paper, we showed how UNA-SUS/UFMA took advantage of this new perspective on distance education to reach students living in remote areas where Internet access is limited, important obstacle to the completion of courses in this modality of education. Using the HTML5 markup language and the techniques of Responsive Web Design it was possíble to provide online books - the main source of content used in courses offered by the institution - on mobile devices.

The major advantage of this application is that it requires only Internet access once, the one in which the user downloads the app. After that the online book is available on users' devices without the need for Internet access. Therefore, although the students of the institution face problems accessing the Internet, the course content might be always available for consultation and studies.

An Architecture for Continuous Data Quality Monitoring in Medical Centers

Gregor Endler[a], Peter K. Schwab[a], Andreas M. Wahl[a], Johannes Tenschert[a], Richard Lenz[a]

[a] *Computer Science 6 (Data Management), Friedrich-Alexander-Universität, Erlangen-Nürnberg, Germany*

Abstract

In the medical domain, data quality is very important. Since requirements and data change frequently, continuous and sustainable monitoring and improvement of data quality is necessary. Working together with managers of medical centers, we developed an architecture for a data quality monitoring system. The architecture enables domain experts to adapt the system during runtime to match their specifications using a built-in rule system. It also allows arbitrarily complex analyses to be integrated into the monitoring cycle. We evaluate our architecture by matching its components to the well-known data quality methodology TDQM.

Keywords

Medical Informatics; Data Quality; Quality Control; Quality Improvement; Data Collection; Databases, Factual; Group Practice.

Introduction

Data quality is an important concern in data integration scenarios. Integration and data quality influence each other bilaterally. Many data quality issues only become evident if several data sources are available, and integration can benefit from high data quality [1].

In the medical domain, one such integration scenario is created by medical practitioners affiliating into group practices or medical centers [2]. They do so for various reasons, among them financial benefits or better collaborative treatment of patients. To reap these benefits, organization wide planning is required. This in turn makes it necessary to create a general view over the data and processes of every participant's practice. This information is found in the respective local patient-data management systems and databases and may exhibit various deficiencies, like missing entries or wrong values. An integrated central database is fed new and possibly erroneous data from the center's locations continuously.

It is thus not enough to do a single pass of data cleaning over local databases. Indeed, it may even be impossible to validate data at the local databases since practitioners may be unwilling to relinquish control of their system or may be unaware of newly established quality considerations. Thus, central continuous monitoring and improvement of data quality is necessary to support the center. Frequent changes also induce significant software aging [3] in any system dealing with data quality. Data quality systems must be able to evolve with newly arising requirements, especially in the health sector. Medical or legal changes must be implementable by domain experts, since these changes may happen too short-term and too often to allow assigning a programmer for substantial code redesign [4].

Contribution

In this paper, we describe an architecture for continuous data quality monitoring. We start out by giving an overview over the project context, and describe our approach and the resulting architecture. To evaluate the architecture's usefulness, we show how it supports data quality methodology. In conclusion, we briefly discuss the ongoing implementation of a prototype.

MEDITALK

The research project MEDITALK is an example of an integration scenario in the medical domain [5]. A so called practice manager is responsible for controlling a medical center. This role necessitates an overview over the data of all the centers' locations. All local practitioners' data is integrated into a central database in a standard Extract-Transfrom-Load (ETL) process [6]. This solution is already in place at three medical centers, together encompassing 50,000 patients, 80 practitioners, and 3 practice managers. Since new data arises at the local practices continuously, ETL is repeated at set intervals. Copies of all local data arrive at daily intervals in the central database. The practice manager interacts with the system through a controlling application, which essentially provides a predefined dashboard of information about the centers' locations and their data.

Data Quality

Data quality is often generically defined as "fitness for use" [7]. This means that for data to be of high utility, it has to conform to requirements according to its application. We divide data quality considerations into two broad groups. Checking their fulfillment may be conceptionally easy, like verifying the length of a string. It may also be more involved, for instance requiring complex data mining or statistical models. Obviously, the boundary between these two difficulty groups is fuzzy - deciding which group a requirement belongs to is a domain expert's responsibility. Within both groups, requirements are further (sometimes implicitly) classified into the usual data quality dimensions [1,7]. We make the assumption that both groups are important to continuous data quality monitoring in medical centers.

Methods

In a first step, we conducted a literature review focusing on data quality both in general as well as specifically in healthcare. To familiarize ourselves with the domain, we afterwards conducted interviews with the three practice managers involved in MEDITALK. We asked questions about the data quality dimensions most mentioned in literature, their impact on the centers' work and about how detected quality problems had been addressed. We worked with the developers of the integration environment of MEDITALK, and designed an architecture to monitor data quality on top of the existing software.

Results

Literature Review

Many methodologies for data quality improvement have been proposed (see [8] for a survey). A commonality between these is that they offer a bird's eye view of necessary steps for data quality improvement and thus are highly generic. The arguably widest used one is Wang's Total Data Quality Management (TDQM) [9] (see Figure 1). TDQM is suited for continuous monitoring and is open to system evolution - both capabilities important for data quality monitoring in the medical domain. Therefore, we make the assumption that being able to support the TDQM steps is a minimum requirement for any data quality solution to be used by practice managers.

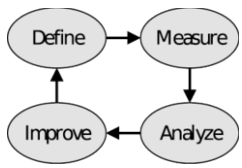

Figure 1 - TDQM cycle

There are many publications specifically considering data quality in healthcare applications, for example health simulations [10], free text analysis of diagnoses [11], or healthcare processes [12]. Concerning data completeness, Miller et al. report about two studies that found "pieces of information perceived as being needed for clinical decisions were missing 13.6% and 81% of the time" [13]. The ACM Journal of Data and Information Quality devoted a special issue to the topic of information quality in healthcare [14]. In 2013, Dixon et al. described the Health Data Stewardship framework and called for software tools to monitor and improve data quality [15]. It follows that supporting high data quality in the medical sector is an ongoing effort.

Interviews

All practice managers reported occurrences of low quality data, with incomplete data being identified as the biggest issue. To be more specific, *population completeness* [1] was deemed the most impactful [16]; a center's practitioners operate on a budget. Once they surpass a certain threshold, their activities are only reimbursed fractionally. This becomes evident at the latest at the end of each fiscal quarter, when practitioners report their activities to a central authority for reimbursement. At this point, however, it is too late for the practice manager to counter this effect. While countersteering would have been possible during the quarter, incomplete data at that time obfuscated arising budgeting problems, leading to loss of revenue.

All practice managers reported that at their centers there already were rules in place about data. Most of these were not checked automatically and had to be evaluated manually. One location reported presence of 119 standardized queries to review some quality constraints, again with the restriction that these queries had to be triggered by hand [17]. This produces significant effort since these queries have to be evaluated frequently. There are some exceptions to this, for example automatic sanity checks performed by patient-data management systems. Still, all practice managers expressed interest in being able to define their own rules for automatic evaluation.

Monitoring Architecture

While our architecture (see Figure 2) is built on top of the MEDITALK packages, it is designed to allow implementation as a standalone application. All user interaction happens through the Interaction package. The Data Service package is responsible for accessing the central database and for storing monitoring results and metadata. Actual data quality measurements are performed by the Monitoring package.

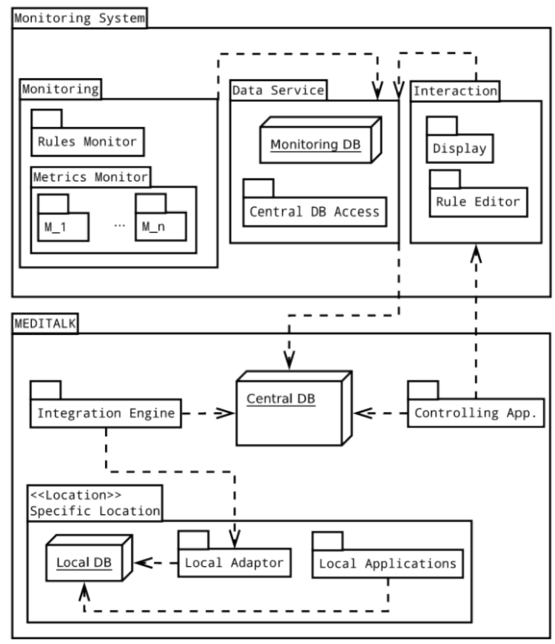

Figure 2 - MEDITALK Integration Environment and Monitoring System

Monitoring Package

Our proposed architecture splits assessment of data quality into two separate concepts: *rules* and *metrics*.

A *rule* is a formulation of a constraint on data, for example R1: ICDCode = 'J00' and Diagnosis != 'Acute nasopharyngitis'[1]. Any tuple in the database for which R1 holds (meaning that the ICD code has an attached diagnosis different from the standard) may be erroneous according to the formulated rule (see [18] for other examples). Another possible form of rules are association rules [19], and conditional functional and inclusion dependencies (see [20] for a survey). Expressing data quality constraints by rules has the advantage that they can be created without intervention by a programmer. Domain experts can formulate rules according to their own requirements.

The **Rules Monitor** package keeps track of the rule base stored in the Monitoring Database, executes rules according to their schedule and in turn stores the results. Rules fall into one of two categories: aforementioned examples are *data quality rules*, and define the fitness of data entries. The second category are *improvement rules*. These are used to trigger events to improve data quality, for example alerting the practice manager to violating data or performing automatic edits[2]. All rules are checked on the available data according to a set schedule. For the MEDITALK project, it is enough to check them once every 24 hours because data arrives in daily intervals. For other contexts, the intervals can be changed according to need. Every rule can also be triggered manually.

[1] This is not necessarily a practical example – we only use R1 to exemplify our system's usage.

[2] Automatic edits bear some challenges like conflicting edits [21]. We assume the practice managers to be aware of these perils.

The **Metrics Monitor** contains all functions that implement metrics, and triggers recalculation according to the needs of the respective metrics. A *metric*, for our purpose, is defined as any measure indicating the quality of a data item or set of data items. In distinction to the mathematical definition of a metric, we denote not only a distance between a data item and its theoretical perfect quality counterpart by the expression "metric", but any indicator which makes a statement about data or data quality. As an example, the number of NULL values within a database table may indicate the table's completeness (depending on NULL semantics [22]). We use the term metric interchangeably as the indicator delivered or the mechanism to calculate the indicator.

We distinguish between metrics and rules for the following reasons: some desirable functions, for instance statistical models (see [23] for an example), may be too complex for easy representation by rules. Also, some rules may prove to be of interest to more than one center. In the case of large sets of rules, creating these rules at all interested centers would be redundant. Expending onetime effort encoding or generating the set in a metric, then integrating the resulting module at each center would lower overall effort. So if for these reasons additional programming is warranted, an additional metric is created. This will usually be done by a programmer in response to a new requirement by a domain expert.

Data Service Package

All results of calculations within the Monitoring package are stored in the **Monitoring Database** to encapsulate all information necessary to assess gathered indicators. A monitoring result is a statement about data, valid at a certain point in time. Each result is identified by;

- the originating rule's / metric's identifier,
- the date and time the result was obtained, and
- all involved tuples and attributes.

Apart from this identifying data, each issue has a payload according to the specific rule / metric, for example an indicator calculated by a metric. The payload may be empty if all necessary information is already present in the result's key, but may also be arbitrarily complex, for example delivering an XML data structure. Usually, a rule's payload will be the percentage of applicable tuples it holds on, and the identifiers of violating tuples. The payloads of metrics may be as simple as a single indicator (e.g. "expected number of patients tomorrow: 32"), possibly including a confidence interval for the value. They may also deliver structures of any number of values and of any depth (e.g. a decision tree derived from patient data).

The **Central Database Access** package serves as a mapper between the Central Database and the data requirements of the Monitoring System. This decouples the Central Database and all other packages that need access to it, preventing changes at the Central Database from propagating to other parts of the system.

Interaction Package

Through the **Rule Editor**, practice managers can define their own data quality rules. This solution has several advantages in comparison to the standardized queries used to date:

- Rules can still be triggered manually, but can also be checked automatically and periodically (at set execution intervals).
- Rules can not only be defined on data, but also on metadata, meaning that rules can be used to alert the practice manager when a metric (or even another rule) changes.
- Drag-and-drop generation of rule conditions may lower initial training effort compared to explicitly spelling out the queries.

The prototypical rule editor (see Figure 3) developed in our group [24] can be used to create Boolean rules, for example to check whether a value matches a regular expression. Users can write their own regular expressions, or choose from standard checks like string length or number format. The editor is able to recreate the standardized queries, and can be extended to allow (conditional) functional dependencies and other kinds of rules not yet implemented.

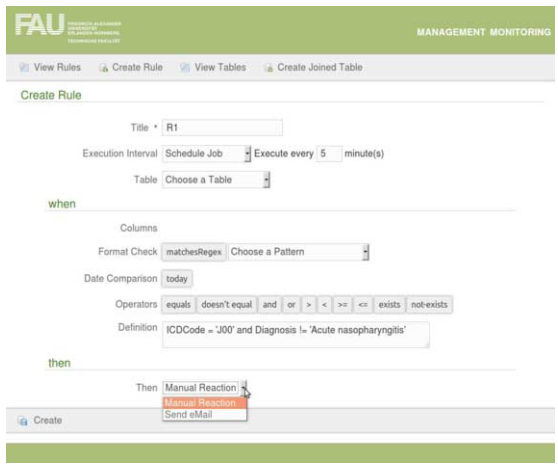

Figure 3 - Rule creation

The **Display** package is responsible for visualizing the state of the Monitoring System. This includes all existing rules and metrics as well as their results on the currently available data. It also enables exploratory analysis of the central database to get an overview over schema and extension. All subpackages of Interaction have their own user interfaces, which can be used on their own or be implemented as plugins for the controlling application in the MEDITALK package.

Discussion

To evaluate whether our architecture is capable of continuous data quality monitoring, we show that each step of TDQM is supported by one or more packages of our architecture, as stated in Figure 4.

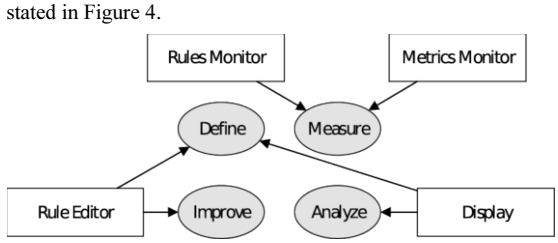

Figure 4 - Supporting TDQM

Define

"The definition component of TDQM cycle identifies important data quality dimensions (...) and the corresponding data quality requirements." [7, p.5, "The TDQM Cycle"]

Defining fitness of data is closely tied to an organization's business goals. As such, some of the effort expended in this step is outside of the scope of the Monitoring System. The

Display package assists in this effort by delivering an overview over available data and the schema of the central database. The formal definition of data quality requirements however is supported by the **Rule Editor** in full.

Example A practice manager (PM in the following) discovers that at some locations, ICD code and diagnosis text are both entered manually. The PM decides that mismatches between ICD code and diagnosis should be avoided, and formulates rules to check for these mismatches. One of these rules is R1: ICDCode = 'J00' and Diagnosis != 'Acute nasopharyngitis'. A catalog of like constraints to check the quality requirement "ICD code and attached diagnosis may not mismatch" is defined.

Measure

"The measurement component produces data quality metrics." [7, p.5, "The TDQM Cycle"]

The measure step is performed by the **Rules** and **Metrics Monitoring** packages. Both calculate indicators for data quality and store them in the Monitoring Database.

Example A new practice joins the center. Once its data becomes available in the central database, Rules Monitoring checks whether all applicable rules hold. Assuming the practice uses the diagnosis "common cold" instead of "Acute nasopharyngitis" in 5 cases with ICDCode = 'J00', all of these fulfill R1. A result is placed in the Monitoring Database stating that 5 tuples (the ones coming from the new practice) fulfill R1 and therefore are of low quality.

Analyze

"The analysis component identifies root causes for data quality problems and calculates the impacts of poor quality information." [7, p.5, "The TDQM Cycle"]

The Analyze step is supported by the interaction of the **Monitoring Database** and the **Display** package. The Display package shows all Monitoring results. It allows drilling down into their information, showing affected tuples and attributes, their provenance, and involved rules and metrics.

Example The result R1 match ratio: 0.13% is shown in the Display package (see Figure 5). This means that out of all diagnosis entries on the central database, 0.13% violate the data quality requirement defined by R1. The PM checks the definition text of the rule as well as which tuples are involved and their provenance. In this way, the new practice is identified as the origin of the problem.

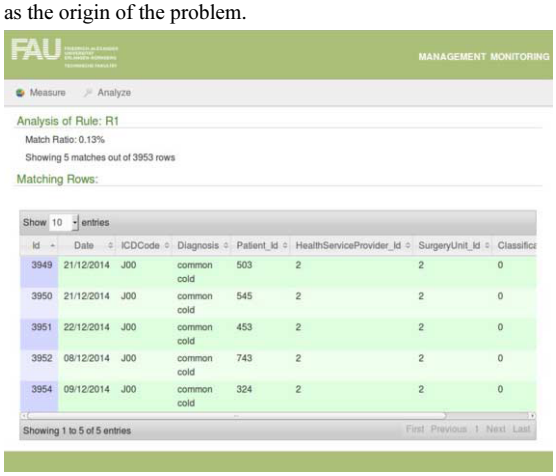

Figure 5 - Analyzing a data quality rule

Improve

"(...) the improvement component provides techniques for improving data quality." [7, p.5, "The TDQM Cycle"]

Again, some of the actions performed during this step are outside of the scope of the Monitoring System (e.g. organizational changes or in-service training of staff). However, the **Rule Editor** can be used to establish improvement rules. An example of such a rule is sending an email to a location that has not entered data by a certain deadline. Data cleaning rules such as automatic edits can also be formulated.

Example Judging the low data quality to be a one-time problem, the PM instructs the new practice to revise the offending tuples. Should the problem occur again, an improvement rule can be created that on detection of a violating tuple either notifies the person responsible or automatically changes the values to conform.

Conclusion

We described an architecture supporting continuous data quality monitoring for medical centers. Lenz identified several important factors in making software sustainable [25]. Our architecture satisfies two of these by design. *Separation of Concerns* is granted by grouping functionality into fitting packages, separating rules, metrics, data access, and user interaction into their own packages. This minimizes the probability that change in one package requires redesign of others. *Deferred Design* is satisfied by the presence of the rule editor and rule monitoring: The set of rules is not hardcoded into the system, but can be built, corrected, and extended at runtime by domain experts as demand requires. This ensures evolvability of the rule system with changing requirements. Two additional factors, *Loose Coupling* and *Service Oriented Architecture*, are implementation specific.

While our application example is an integration scenario, this is not imperative. Since the architecture only requires access to a single central database and not the sources, it can just as easily be applied to databases that are not involved with integration, for example hospital information systems. This design does not diminish the potential to make use of information that arises in the ETL process: Any data and metadata that is stored in the connected database is fair game for monitoring.

By enabling continuous monitoring, system evolution and deferred design by domain experts, we also support frameworks like Health Data Stewardship (HDS) [15]. The connection to health outcomes that HDS demands is implemented by the system's ability to monitor any kind of data. Since outcomes may also be stored in the central database, any information about those can be used by rules and metrics as well as in the display component.

Several parts of the architecture are already implemented. We are currently developing methods for measuring population completeness. Access to the central database is handled directly through the accessing components and not through a common mapper as of now. Monitoring DB and Display are not yet complete, but are already capable of storing respectively presenting the results of rules. Rule Editor and Rule Monitoring are fully functional. Once complete, we will evaluate the effectiveness of our solution through user studies.

A Conceptual Framework for Decision-making Support in Uncertainty- and Risk-based Diagnosis of Rare Clinical Cases by Specialist Physicians

Adriano A. Santos[a], J. Antão B. Moura[b], Joseana Macêdo Fechine Régis de Araújo[b]

[a] *Graduate Program in Computer Science from the Federal University of Campina Grande - UFCG*

[b] *Systems and Computing Department - Federal University of Campina Grande – DSC/UFCG, Brazil*

Abstract

Mitigating uncertainty and risks faced by specialist physicians in analysis of rare clinical cases is something desired by anyone who needs health services. The number of clinical cases never seen by these experts, with little documentation, may introduce errors in decision-making. Such errors negatively affect well-being of patients, increase procedure costs, rework, health insurance premiums, and impair the reputation of specialists and medical systems involved. In this context, IT and Clinical Decision Support Systems (CDSS) play a fundamental role, supporting decision-making process, making it more efficient and effective, reducing a number of avoidable medical errors and enhancing quality of treatment given to patients. An investigation has been initiated to look into characteristics and solution requirements of this problem, model it, propose a general solution in terms of a conceptual risk-based, automated framework to support rare-case medical diagnostics and validate it by means of case studies. A preliminary validation study of the proposed framework has been carried out by interviews conducted with experts who are practicing professionals, academics, and researchers in health care. This paper summarizes the investigation and its positive results. These results motivate continuation of research towards development of the conceptual framework and of a software tool that implements the proposed model.

Keywords:

Conceptual framework; Risk; Uncertainty; Clinical Decision Support Systems.

Introduction

Clinical Decision Support Systems (CDSS) provide medical professionals with knowledge at appropriate time, and in appropriate form. In general, they ease decision-making process, making it efficient and effective, helping to reduce the number of avoidable medical errors and enhancing quality of treatments provided to patients [1].

Having this in mind, much research has been developed in order to provide both specific solutions (Specialized Systems) [1], [6], [7] and general ones (conceptual frameworks) [2], [3], [4], [11] that can help Specialist Physicians in reducing the number of medical errors; reducing duration of appointments; managing knowledge or even creating new clinical procedures which may become a standard for the entire medical team. Nevertheless, there is a category of clinical cases which deserve more caution: the rare cases.

According to Loriggio [8], when a problem presents difficulties associated to the unavailability of solution or demands too many resources (money, staff, time, information about environmental elements, etc.) and, therefore, too much effort for solving or diagnosing its causes, such a problem is said to be complex or rare. We can infer that these problems are directly connected to lack of: knowledge about the rare case; reliable and available sources; sharing and exchange of knowledge and learned cases; more precise analyses; and evidence raising.

Day after day, specialist physicians carry out complex health analyses and must make decisions which might be fatal, in case they were erroneous. Very often, rare cases are found and methods that allow reduction of uncertainty about procedures must be executed in order to settle risks associated with the decision. Urgent clinician-clinician communications require routes of contact that are fast and dependable and allow for exchange of complex information [10].

In an attempt to contribute to the solution of rare clinical cases, this work tries to answer the following questions: how can one mitigate risks and uncertainty that challenge specialist physicians when analyzing an unfamiliar clinical case? Which technologies and/or techniques could be harnessed to create a conceptual framework to give support to decision-making process in a clinical environment?

This paper proposes a conceptual framework for helping in the analysis and decision-making process of rare clinical cases with basis on the association of medical evidence analysis techniques, knowledge management, and collective intelligence in order to mitigate the risks and uncertainty faced by specialist physicians. Another important characteristic of the proposed framework is as a controlled teaching and learning tool with the possibility of formalizing a process for aiding training of specialist physicians,.

In fact, we anticipate that the most likely use of our model will be in the education, to help train health professionals. The educator can set up controlled cases and submit them to physicians being trained, so that they can give their opinions, in a simulated environment. Thus building knowledge by means of interactions among the students. At the end, the educator can evaluate the interactions and even suggest more sources or procedures in order to consolidate or generate more significant knowledge.

Hypotheses

We tested the following hypotheses in this research:

H_a: The proposed framework will be of help in the decision-making process in rare clinical cases.

H_b: The proposed model can be used as a tool for knowledge management and for professional training of specialists.

H_c: Decision makers are satisfied with the proposed framework and can identify effective contributions to this area.

Related Work

The first studies that we can refer to, in the context of this research, were conducted by Dobrow et al. in 2004 [2], first version, and Dobrow et al. in 2006 [3], an evolution of the previous version. The authors´ decision-making approach is based on evidence techniques in public health. They defend that evidence and context are integral and fundamental components for evidence-based decision process. The authors present a conceptual framework which aims to analyze the impact of use of context in constitution of evidence and how evidence is used in medicine. They make use of an "evidence source" or, technically, a knowledge base, and consider the role of context in the introduction, interpretation, and application of evidence to support the decision-making process.

The studies conducted by Dobrow et al. in 2004 [2] and Dobrow et al. in 2006 [3] are related to this research because they deal with a conceptual framework and use the evidence concept. However, they are limited to focusing on how context impacts on what constitutes evidence and how that evidence is utilised. They do not use other knowledge sources or processes to improve the decision-making process.

In work by Ferreira et al. in 2007 [4], a framework for the decision process in emergency cases is presented. The authors use database management systems (DBMS), a specialist's base, and a geographic information system (GIS); to plan tasks which will help reduce the time necessary for strategic planning in response to emergency cases. The framework also features an auxiliary module for simulation of cases. The work by Ferreira et al. [4] is similar to our proposal due to the use of a specialist database and to the purpose of reducing response time of clinical cases. However, the knowledge sharing process, the treatment of uncertainty and the management of learned cases presented in our proposal were not covered by the authors' work.

Lopes et al. 2009 [7], proposed a decision support conceptual framework based on evidence, context, and cases called EcoCADe (Evidence, Context, and Cases to Support Decision). The authors proposed a hybrid solution in GIS and CBR (Case Based Reasoning), allowing specialists to model evidence of PBE (Evidence-Based Practice) domain, both using problem context. The authors proposed a solution that does not depend on a specific domain, which allows its adaptation to several domains. A methodological approach to support the decision-making process involved RBC techniques and/or PBE procedures. The authors validated the model both in legal and medical contexts. It is a robust and adaptive solution which uses concepts that are part of the basis of our work. Nevertheless, risk and uncertainty factors, collective knowledge process as support to decision-making process, which are present in our work, were not covered by those authors' work.

Kastner and Straus 2012 [6], proposed a conceptual framework used in the development of a support tool for clinical decision of osteoporosis cases. The authors exposed security problems in the use of information systems in the process of supporting decision-making in clinical cases. They developed a solution that uses Knowledge-to-Action cycle and stages of the Medical Research Council framework. That work is of interest to our research because it raises a set of issues and possible problems in the use of information systems as support tools for the decision-making process in medical systems. The authors created an expert system with the objective of supporting diagnosis of osteoporosis problems. We do not propose development of an expert system, but a domain-independent framework, such as EcoCaDe. Even the development of an IS solution for future validation, could be made flexible and adaptable to the desired domain.

Minutolo and collaegues 2012 [9], proposed a knowledge editing system based on standards to direct and help in creation and formalization of clinical recommendations, to be used in knowledge-based Decision-Support Systems. That system was conceived to offer a set of standards that ease insertion and editing of clinical recommendations, using the combination of knowledge representation techniques to instantiate standards in knowledge bases, using rules built by using ontologies. That research is related to our work because it involves a hybrid solution that also enables management of knowledge generated by the environment. However, as in the work of Kastner and Straus [6], it is a specialized software.

Table 1 summarizes a comparison of this paper and related works reviewed here.

The Proposed Conceptual Framework

Our framework comprises five macro stages, presented in Figure 1, namely: a) Anamnesis Process; b) Knowledge Management; c) Decision Strategy; d) Application of Procedures; and e) Learned Lessons.

Each stage presented in the framework comprises a set of pooled techniques which receives, sequentially, the outputs of previous stages. The specialist physician in charge of the analysis of the case is responsible for the Anamnesis, Knowledge Management, and Application of Procedures stages. The Decision Strategy stage makes use of Delphi method in an attempt to achieve convergence of the opinions of experts in the decision-making process. The end of the process is the generation of a new case, which is stored on the Learned Lessons database.

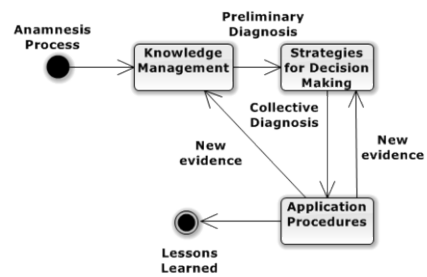

Figure 1– The conceptual framework

In the Anamnesis Process stage, the specialist physician interviews the patient in order to gain as much information as possible about her condition. This stage comprises three steps, namely: a) Questions (Open, Focuses – or Semi-open, Closed, Directed, and Composite); b) Collecting (Answers); and c) Observed evidences (previous analyses based on the survey carried out). The output of this process is a clinical evidence list, which will be used as input by the Knowledge Management stage.

In the Knowledge Management stage, the specialist physician checks the evidence collected in the Evidence step in two knowledge sources, attempting to find consolidated evidence that may serve as basis for a preliminary diagnosis.

The first knowledge source used is based on reliable external sources, and uses an evidence search engine. The second knowledge source is a knowledge base formed by the set of lessons learned with the experiences of the solved cases and the experience of the specialist physicians.

The output of the Knowledge Management stage is a Preliminary Diagnosis of the specialist physician. This information is sent to the third stage of the process, called Decision-Making Strategies.

In the Decision-Making Strategies stage, preliminary diagnosis is evaluated by a set of specialist physicians, characterizing the Collective Intelligence process. The formalization of this stage uses Delphi method [5], so that the expert does not make biased decisions for reasons such as marriage and friendship with other experts, and especially because it will be possible to share opinions among themselves to the point of reaching a consensus.

The decision-making task of a specialist physician faced with a rare situation is highly risky, as said in the introduction of this work. However, we believe that, joining the Delphi method and the Collective Intelligence process, as proposed in this stage, with the analysis of the contributions of other specialist physicians will mitigate the risks, because these specialist physicians will contribute their practical experiences, since they have knowledge about the studied domain.

The contribution of experts is possible due to the controlled feedback that defines regular communication between participants in the discussions of previous rounds summaries, reducing noise in communication and avoiding the diversion of the main discussion of the problem. During the rounds of discussions, experts receive information and comments of others, and may change or provide their thoughts with more appropriate arguments [5].

The output of the Decision-Making Strategies stage is a collective diagnosis, which will be used by the specialist physician, who started the process, in the Application of Procedures stage.

The Application of Procedures stage, is actually where the specialist physician applies the clinical procedure to the patient. The result of this stage may generate other evidence which, according to the specialists' decision, can be fed back to the Knowledge Management or the Decision-Making Strategies stages; in case the procedure proposed by the collective diagnosis is not successful (e.g: medications and drug allergic reactions). However, if the procedure is successful, the whole case becomes a Learned Case and it is stored on the Learned Lessons base, with the possibility of being used as a source of information for new cases.

Clinical Decision Support Systems for Analysis of Unfamiliar Clinical Cases (CDSS-AUCC)

Implementation of the Clinical Decision Support for analysis of unknown clinical cases (CDSS-AUCC) tool (Figure 2), including all modules in the proposed framework, is ongoing. CDSS-AUCC will be fully Web compatible and make use of a Business Process Model and Notation (BPMN) service to business rules. The system will be evaluated in a case study. Later, it will be used as a decision-making support tool in a school clinic; and also as an environment aid in the education and the training of health experts at a university in the state of Paraíba, Brazil.

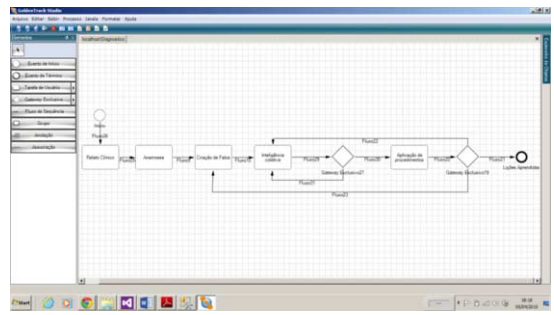

Figure 2–Clinical Decision Support for analysis of unknown clinical cases (CDSS-AUCC)

As of writing this paper, a first version for each of the modules that represent the processes of: a) Anamnesis Process (Figure 3); b) Knowledge Management (Figure 4); c) Decision Strategy (Figure 5); and d) Application of Procedures (Figure 6) are already implmented. Leaving only the Learned Lessons. Development is ongoing to produce evolutionary – in terms of functionality and performance – versions for each module.

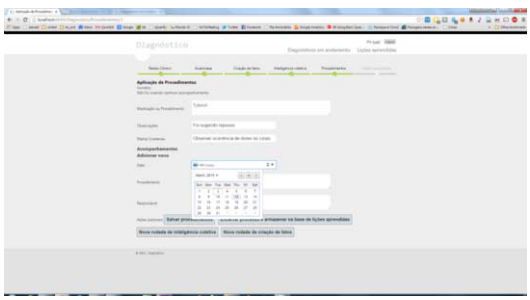

Figure 6– Application of Procedures

Methods

This research is classified as an applied and qualitative research. It aims to get the opinion of a group of health experts (target audience of the research) on the feasibility and the applicability of the proposed framework.

The results of the literature review helped to develop questions for the semi-structured interview protocol presented. Then, data were collected through a survey and interviews for experts' perspectives and recommendations on the dissemination of computer decision support software and the conceptual framework.

Interviews were conducted with 20 experts who work in Brazil's northeastern state of Paraíba as health professionals, academics, and researchers. Practitioners were, preferably active in private or public hospitals. Among the selected professionals were eight cardiologists, two geneticists, four mental nursing specialists, two physiotherapists, two specialists in gastroenterology, and two ophthalmologists. Three specialists have private clinics and four coordinate undergraduate courses in medicine in their respective educational institutions. Four of the experts coordinate scientific research projects.

We wanted to know their opinions and formalize these opinions into a document which would guide us through the rest of the research. The questions presented to them were:

A. Can we believe the proposed framework will be of help in the decision-making process in the diagnosis of rare clinical cases?
B. Can the proposed model be used as a tool for knowledge management and for professional training of specialists?
C. As a decision maker, are you satisfied with the proposed model and could you identify any effective contribution to this area?
D. Would you use an IT tool based on this model to support your decisions?
E. Do you consider the model useful and would you invest (time, specification effort, etc.) in its evolution?

We and the interviewed experts used the Think Aloud Protocol [12]. In addition to offering comments and suggestions, the experts answered the questionnaire with questions A) to E) above. Possible questionnaire responses were in the form of a 4-level Likert scale: Strongly disagree = 0; Disagree = 1; Agree = 3; and, Strongly agree = 4.

Experimental Unit

As an experimental unit, we selected a group of experts in health who work in private and public clinics in northeastern Brazil. All participants are professors of medical schools at public and private universities, with at least a master degree (eight have doctoral degrees), and minimum professional experience of five years. Furthermore, 70% of them also function as researchers.

Experimental Design

Twenty interviews were performed as described. Each interview lasted an average of two hours. Interviews of experts were conducted in two steps: in the first step, after the presentation of the framework and the system, the interviewees reported their opinions orally and subsequently questioned about the system usability. For this step, we used the principles of the Think Aloud protocol. In the second step, the experts answered the questionnaire. This questionnaire was created to analyze the prevalence of opinions of experts over the research objectives and also give answers about the hypotheses for this research.

Results

Statistics

We used an ordinal scale on the answers to questions A, B, and C; performed median tests (Wilcoxon test) with the degree of reliability of 95%, and the ratio test. The results are shown in Table 2.

Table 2– Statistical tests results

Question	V	p-value	Delta	Conf. Interv.
A	91	0.0001	0.209037	0.44 - 0.85
B	78	0.0003	0.214703	0.38 - 0.81
C	65	0.011	0.219130	0.28 - 0.71

All the experts said they would use an IT tool based on the model and confirmed interest in contributing to the development of research.

Graphics

The results of the experiment for questions are given in figure 7.

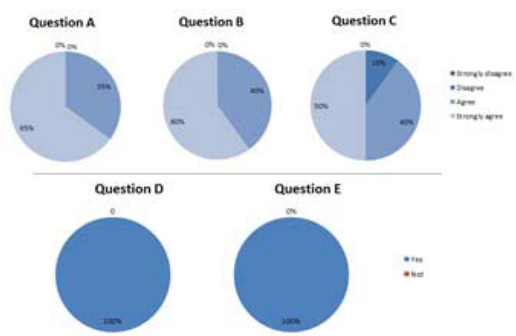

Figure 7– Results of the experiment

Discussion

The main aim of this research is to analyze whether the proposed framework has an effective contribution in the decision-making process in unfamiliar clinical cases. Therefore, hypothesis H_a, H_b, and H_c were raised and submitted to representative experts, so they could give their appraisal.

For preliminary validation of the usefulness of the proposed framwork, we interviewed twenty health professionals who function as professors, researchers, and practitioners in medical area. They went through two stages of analysis (Think Aloud and Face Validity) and answered a questionnaire to a) assess whether they *thought* the proposed framework was valid for their decision-making process, b) whether it would be useful in the teaching process and c) continuing training of new specialists; and whether there would be scientific contribution to the field of rare cases diagnosis.

According to the results found in the processing of statistical tests and the descriptive data analysis, one may conclude that, in the opinion of experts, the conceptual framework was approved as a contribution to the medical area and it will bring benefits to the educational process, training of new specialists, and to the professional field in general.

The development of a solution that implements the proposed framework was also considered promising since all the involved specialists offered to participate in the development and evolution process of the research.

The group of experts selected for this research, came from different backgrounds, interests and specialties which made for a rich and heterogeneous sample in perceptions. They put forward their real needs and directly contributed to the evolution and development of the research.

Thus, according to all the points raised, the null hypotheses is rejected ($p < 0,05$). Therefore, stimulating continuation and development of the research.

Conclusion and Outlook

This research aims to explore the opinions of experts in the health area on a conceptual framework to support decision making, mitigating risks and uncertainties faced by experts in unfamiliar clinical cases. The conceptual framework proposed in this paper is based on five stages: Anamnesis Process, Knowledge Management, Decision Strategy, Application of Procedures and Lessons Learned.

For preliminary validation of the usefulness of the proposed framwork, we interviewed twenty health professionals who function as professors, researchers and practitioners in medical area. They went through two stages of analysis (Think Aloud and Face Validity), and answered a questionnaire to assess whether they *thought* the proposed framework was valid for their decision-making process; whether it would be useful in the teaching process and continuing training of new specialists; and whether there would be scientific contribution to the field of rare cases diagnosis. Their positive answers motivate continuation of the research; and development of the conceptual framework which will lead to availability of a software tool that implements the proposed model.

As for future work, we will concentrate on the completion of the development of the CDSS-AUCC tool – a software tool that implements the proposed framework – and on the study of cases with more clinical experts for further validation of the model.

Abstract

Recently there has been an increasing interest in applying information technology to support the diagnosis of diseases such as cancer. In this paper, we present a hybrid approach using case-based reasoning (CBR) and rule-based reasoning (RBR) to support cancer diagnosis. We used symptoms, signs, and personal information from patients as inputs to our model. To form specialized diagnoses, we used rules to define the input factors' importance according to the patient's characteristics. The model's output presents the probability of the patient having a type of cancer. To carry out this research, we had the approval of the ethics committee at Napoleão Laureano Hospital, in João Pessoa, Brazil. To define our model's cases, we collected real patient data at Napoleão Laureano Hospital. To define our model's rules and weights, we researched specialized literature and interviewed health professional. To validate our model, we used K-fold cross validation with the data collected at Napoleão Laureano Hospital. The results showed that our approach is an effective CBR system to diagnose cancer.

Introduction

According to the World Health Organization (WHO), cancers figure among the leading causes of morbidity and mortality worldwide[1]. Researchers from the WHO and the International Agency for Research on Cancer (IARC) claim that in 2012, there were 14.1 million new cancer cases and a total of 8.2 million deaths from cancer worldwide. It is expected that the number of cancer patients will continue to rise by about 70% over the next 2 decades[1]. Early diagnosis of cancer is a big challenge because it is a disease with multiple locations and clinicopathological aspects while having no pathognomonic (i.e., specific to each disease) signs or symptoms[2]. Therefore, it can be detected in various stages of histopathological and clinic evolution. Healthy lifestyle and early diagnosis of this disease can reduce its mortality rate, according to the International Union of Cancer Control (UICC)[3].

Many researchers have applied Artificial Intelligence (AI) techniques to create health-related systems or models, such as the diagnosis or classification of diseases [1-4]. To diagnose cancer, researchers applied different computational techniques. Salem and El Bagoury [5] proposed a hybrid case-based adaptation model, that combines transformational and hierarchical adaptation techniques with artificial neural networks and certainty factors for the diagnosis of thyroid cancer. Zubi and Saad [6] combined data mining techniques with neural networks for the early diagnosis of lung cancer. For the diagnosis of breast cancer, Keles, Keles and Yavuz [7] used neuro-fuzzy rules while Sharaf-elDeen et al. [8] used a hybrid approach that combined case-based reasoning (CBR) with rule-based reasoning (RBR).

In this paper, we present a hybrid approach using CBR and RBR to assist healthcare professionals in the early diagnosis of patients with cancer. We use CBR and RBR because rules and cases are complementary [9]. Instead of using RBR as an alternative solution to CBR, as Sharaf-elDeen et al. [8] did, we use it to improve the probability of CBR to converge to the best solution. The proposed model may act both as a decision support system for less experienced clinicians and also as a second opinion for experts.

To carry out this research, we received the approval of the ethics committee at Napoleão Laureano Hospital. To define our model's cases, we collected real patient data at Napoleão Laureano Hospital, which is a reference for oncology in Brazil. We represented the case with patients' personal information, signs (i.e., objective findings that can be described by a health-care provider), symptoms (i.e., subjective complaints reported by patients), and their diagnoses. To define our model's rules and weights, we researched specialized literature [10] and interviewed a general practitioner.

For the purpose of this research, we collected data from patients with gastrointestinal cancer. More specifically, patients with the following gastric neoplasms: anal, colorectal, esophagus, and stomach. To validate our model, we developed a prototype and used the K-fold cross validation method. The final results show that our approach has increased the accuracy of the diagnosis by 22.92% when compared to using only CBR.

Background

Case-based reasoning

Case-Based Reasoning is a paradigm for solving problems that is fundamentally different from other major AI approaches. Instead of relying solely on general knowledge of a problem domain, or making associations along generalized relationships between problem descriptors and conclusions, CBR is able to use specific knowledge of previous experiments from concrete problems (cases) [11]. In CBR, a new problem is solved by reusing the solution of a previous

[1] http://www.who.int/mediacentre/factsheets/fs297/en/
[2] http://www2.inca.gov.br/wps/wcm/connect/tiposdecancer/site/home/estomago/diagnostico_profissional
[3] http://www.uicc.org/national-cancer-leadership-congress-2014

similar problem. A second important difference is that CBR is an incremental approach. This means that each time a problem is solved, this new experience is retained, making it immediately available for future problems [12].

The processes involved in CBR can be represented by a schematic cycle (Figure 1), which is comprised of the tasks of retrieving the most similar case, reuse/adapt the case to try to resolve the problem, revise the proposed solution if necessary, and retain new solution as part of a new case.

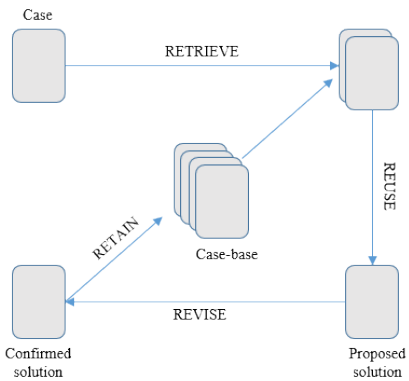

Figure 1 – CBR cycle, introduced by Aamodt and Plaza [11]

CBR can be integrated with other techniques. Marling et al. [13] present CBR integration with RBR and constraint-satisfaction problem (CSP) solving. Furthermore, they discuss CBR integration with model-based reasoning (MBR), genetic algorithms, and information retrieval. RBR was the first modality to be successfully integrated with CBR [13].

Rule-based reasoning

RBR is a methodology whose representation of knowledge is in the form of IF–THEN rule statements. Rules are patterns, so the RBR engine searches for patterns in the rules that match patterns in the data. RBR is an ideal approach for solving simple problems in which there are few rules [14]. In RBR, the problem solving complexity is directly proportional to the number of rules necessary to match the pattern of data. Furthermore, RBR lacks the ability to learn due to the difficulty of acquiring new expertise in pattern matching or new rules [14].

The basic form of a rule is the following:

```
IF <conditions>
THEN <conclusion>
```

where <conditions> represents the rule conditions, and can be connected by logical operators such as AND, OR, NOT, etc., forming a logical function. When rule conditions are satisfied, the <conclusion> is derived and the rule is said to "trigger" [9].

Methods

In medical decision support systems, the use of CBR or RBR methodologies is common [15]. In the proposed approach, we used CBR as the main reasoning process, and RBR was used to improve part of this process. The idea is that our approach can be used in a system that assists the physician in the early diagnosis of cancer. During a medical appointment, the patient tells the doctor some personal data and the symptoms that he/she is feeling. The physician will add this information to the system along with the signals perceived by the patient. The system will search in the database for the most similar case to that of the patient. Based on this result, the doctor may state the prognosis, and request tests to confirm the presence or absence of disease (Figure 2). The proposed model may act both as a decision support system for less experienced clinicians and as a second opinion for experts.

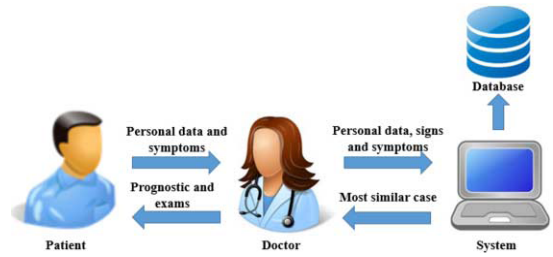

Figure 2 – System representation

Our methodology is composed of four main steps: data collection, case representation, similarity measures definition and rules definition (Figure 3). The first step is necessary for both the CBR application and also the RBR. The second and third steps correspond to two basic elements of a CBR system [12] and the fourth stage corresponds to RBR methodology. We applied RBR to define the case's attribute weights, used in the global similarity function.

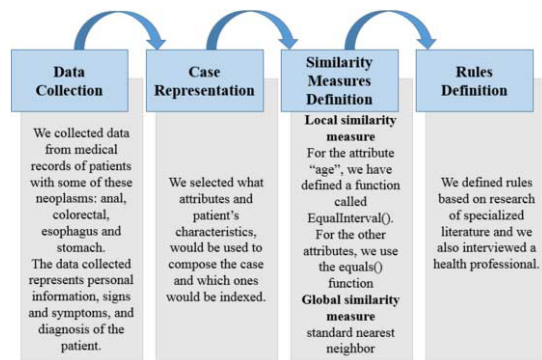

Figure 3 – Main steps of the methodology

In the following subsections, we present in more detail the four steps of our methodology.

Data Collection

With the approval of the Napoleão Laureano Hospital ethics committee, we collected data from the medical records of patients. We kept the privacy of their data. We collected the medical records ID from the agenda of the specialist in gastrointestinal cancer and we focused, more specifically, on patients with the following gastric neoplasms: anal, colorectal, esophagus and stomach.

The data collected corresponds to some personal information such as age, family history, signs and symptoms such as cutaneo-mucosal pallor and dysphagia, respectively, and the diagnosis of the patient. It was not possible to collect all the data we would have liked because some records had little information about the signs and symptoms of the patient. Furthermore, many of them had little digitalized infomation, hindering our collection process.

In this research, we used forty-eight cases from real patients: six cases of patients with anal cancer, six with esophageal cancer, fifteen with colorectal cancer, and twenty-one with stomach cancer.

Case Representation

To represent the cases, we used a set of [attribute – value]. An [attribute – value] system is a basic knowledge representation framework comprising a table with columns representing attributes and rows representing objects. Each table cell therefore designates the value (also known as the "state") of a particular attribute of a particular object. In this work, each object is a case and can be represented by a problem, personal data, signs and symptoms, and also by a solution, the diagnosis (Figure 4).

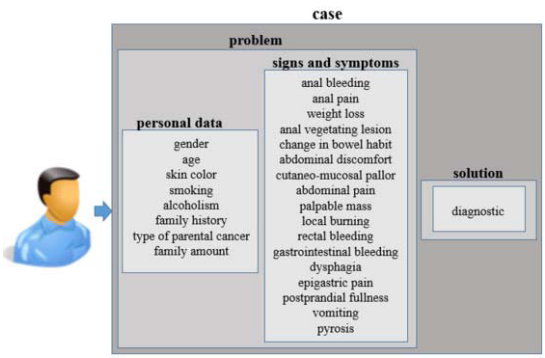

Figure 4 – Representation of the case in the proposed approach

In our approach, a case consists of twenty-six attributes, most of them boolean (i.e., they assume true or false values). Types and the respective values of the remaining attributes can be viewed in Table 1.

Table 1 – Attributes Configuration

Attribute	Type	Value
gender	String	male / female
age	Integer	1 to 110
skin color	String	white / brown / black
smoking	String	non-smoking / smoking / ex-smoking
alcoholism[4]	String	non-alcoholic / alcoholic / ex-alcoholic
family history	String	none / 1º degree / 2º degree / 3º degree
type of parental cancer	String	none / mouth / colorectal / stomach / eye / ovary / lung
family amount	String	0 / 1 / >1

Similarity Function Definition

Each attribute in a case is a piece of information about the case. An important attribute for the recovery process is called the "attribute index". Each index has a set weight, which represents the importance of that attribute in the recovery process, and is typically instantiated by the user with a value between 1 and 10.

The recovery process is based on a similarity function. In this work, we used the standard nearest neighbor method [12]:

$$sim(Q, C) = \frac{\sum_{i=1}^{n} f(Qi,Ci) x\, wi}{\sum_{i=1}^{n} wi} \quad (1)$$

This function returns the global similarity value between two cases, Q and C. Qi corresponds to the attribute value i of a new case and Ci corresponds to the same attribute i of the case recovered from the case-base. Wi is the weight of i attribute and n is the number of attributes of a case. Thus, n is equal to twenty-three, since the attributes "family history," "number of family", and "prognosis" are not used in the calculation of the equation.

In (1), "f" is the function of local similarity of each attribute. All of them use the local similarity function Equal(), except for the age attribute. For this, a new function called EqualInterval(), which calculates the similarity of the attribute according to age ranges (<= 60, 61-70 and >= 71) defined by us. Thus, for this attribute, the values of 74 and 80 are coded identically.

The twenty-three features used in the calculation of similarity have a default weight of "1". Some attributes have altered weights according to pre-established rules mentioned in the later section. We believe that the weights in general should be chosen by a specialist in gastrointestinal cancer in order to increase the accuracy of the system.

As we have a small case-base, the recovery method that we use is the sequential, that is, the measure of similarity is calculated for all cases of the base [12].

Rules Definition

The rules created and used in our approach were based on information extracted from a medical book [10] and the National Cancer Institute[5] (INCA) website. The weights used in the rules were decided with the help of a general practitioner. We interviewed the general practitioner and used a template to formulate the questions: "How important is the X attribute to diagnose cancer Y?", where X corresponds to the some case attribute and Y to some type of cancer. The answers were collected on a scale from 1 to 10.

1st rule: This corresponds to the patient's family history. Patients who have a relative who has or had a particular type of cancer is more likely to also have cancer. Among the types of cancer studied in this research, only colorectal and stomach cancer consider family history.

Variables	Condition	Action
type_ca_parental	type_ca_parental = colorrectal OR type_ca_parental = stomach	type_ca_parental.weight ← 5

Figure 5 – First Rule

2nd rule: This also corresponds to the patient's family history. If the number of a patient's relatives who have cancer is greater than 1, then the patient will be more likely to also have this neoplasm.

Variables	Condition	Action
amount_family type_ca_parental	amount_family > 1	type_ca_parental.weight ← 8

Figure 6 – Second Rule

3rd rule: Dysphagia is the main clinical manifestation that occurrs in patients with esophageal cancer.

[4] a chronic disorder characterized by dependence on alcohol

[5] National Cancer Institute http://www2.inca.gov.br/wps/wcm/connect/tiposdecancer/site/home

Variables	Condition	Action
dysphagia	dysphagia = true	dysphagia.weight ← 5

Figure 7 – Third Rule

4th rule: According to the data from the literature [10], weight loss is a common feature in patients with colorectal, esophagus, or stomach cancers. However, there are cases of patients with anal cancer that also presented with weight loss.

Variables	Condition	Action
weight_loss	weight_loss = true	weight_loss.weight ← 2

Figure 8 – Fourth Rule

5th rule: Postprandial fullness is a feeling of stomach fullness, and is characteristic of patients with stomach cancer.

Variables	Condition	Action
post_prandial_fullness	post_prandial_fullness = true	post_prandial_fullness.weight ← 5

Figure 9 – Fifth Rule

6th rule: Anal bleeding is the most common feature present in patients with anal cancer [10]. However, patients with colorectal cancer may also exhibit this symptom.

Variables	Condition	Action
anal_bleeding	anal_bleeding = true	anal_bleeding.weight ← 5

Figure 10 – Sixth Rule

7th rule: Anal pain is a feature of patients with anal cancer, but it also appears as a symptom in patients with colorectal cancer.

Variables	Condition	Action
anal_pain	anal_pain = true	anal_pain.weight ← 5

Figure 11 – Seventh Rule

8th rule: A change in bowel habits (diarrhea or constipation) is a warning sign for colorectal cancer. There are cases of patients with stomach cancer who also have this symptom.

Variables	Condition	Action
change_in_bowel_habit	change_in_bowel_habit = true	change_in_bowel_habit.weight ← 5

Figure 12– Eighth Rule

9th rule: Abdominal pain and changes in bowel habits are symptoms of colorectal cancer. They are also often present in patients with stomach cancer.

Variables	Condition	Action
abdominal_pain	abdominal_pain = true	abdominal_pain.weight ← 3

Figure 13 – Ninth Rule

Validation Method and Results

To validate the system, we developed a prototype, and we used k-fold cross-validation [16]. As we have forty-eight cases and the number of cases for each neoplasm is a multiple of three, we split the data into three blocks, each one with sixteen cases.

We used each block as input to the system. First, we made tests without the use of rules (i.e., all attributes independent of the value had a weight of "1"). Then, we redid the tests using the rules previously mentioned. The result of the three iterations can be seen in Table 2, Table 3, and Table 4, respectively.

The diagnosis accuracies by fold and by type of cancer are shown in Table 5 and Table 6, respectively.

Table 2 – Results of the first test block

Nº	Real diagnosis	Without rules		With rules

Discussion and Conclusion

Many researchers have developed different approaches to predict, diagnose, and classify cancers, but in general, only a single type of cancer is discussed. In this research, we focused on four types of gastrointestinal cancer. In addition, we used rules to customize the cases. The diagnosis accuracies by fold

and by type of cancer are shown in Table 5 and Table 6, respectively.

To assess if our approach increased the diagnosis accuracy compared to using only the CBR approach, we used the paired t-test with 95% confidence interval and got p-value = 0.02664, refuting the null hypothesis (H0 = The CBR performance is the same as the proposed hybrid approach). Given this, we confirmed our expectations.

The limitations of this study are related to the quantity and quality of the cases and weights. In addition, we believe that with the help of an oncologist, we could improve the rules and attribute weights. Even though the model training technique used data from a specific population group, the cross-validation results might not be enough to generate adequate data for a reliable model.

In future works, we will extend the case-base, and will seek help from a medical expert to validate the rules and the weights associated with them. Furthermore, we will discuss the remaining phases of the CBR cycle.

Abstract

We examined a process for automating the classification of articles in MEDLINE aimed at minimising manual effort without sacrificing accuracy. From 22,808 articles pertaining to 19 antidepressants, 1000 were randomly selected and manually labelled according to article type (including, randomised controlled trials, editorials, etc.). We applied a machine learning approach termed 'active learning', where the learner (machine) selects the order in which the user (human) labels examples. Via simulation, we determined the number of articles a user needed to label to produce a classifier with at least 95% recall and 90% precision in three scenarios related to evidence synthesis. We found that the active learning process reduced the number of training instances required by 70%, 19%, and 14% in the three scenarios. The results show that the active learning method may be used in some scenarios to produce accurate classifiers that meet the needs of evidence synthesis tasks and reduce manual effort.

Keywords:

Machine Learning; Databases, Bibliographic; Antidepressants.

Introduction

When undertaking reviews or synthesis of clinical evidence, researchers are faced with the task of identifying all relevant published studies in bibliographic databases. This has become increasingly difficult and time-consuming with the dramatic increase in the number of studies being published each year.

To improve the efficiency of evidence synthesis tasks that require the comprehensive identification of specific types of articles, researchers have analytically devised search queries or filters, and applied them to large bibliographic databases such as MEDLINE [1-8]. Others have proposed methods for context-specific searches by partially or completely replacing the need for manual screening and classification using machine learning methods [9-11].

In an effort to maximise the proportion of relevant articles identified (recall) in these searches – which ideally should be 100% for systematic reviews – researchers are often forced to sacrifice the proportion of irrelevant articles also included as relevant (precision), leaving them with many articles that require further manual query and classification.

Here we consider the application of machine learning to the task of article classification, and propose the use of *active learning* [12], an approach aimed at reducing the number of examples that a user (human) needs to provide to the learner (machine). Active learning has been used to classify clinical studies for systematic reviews previously [11], and for well over a decade in biomedical research applications ranging from drug discovery to biomedical informatics [13, 14].

Our aim was to examine whether active learning could be used to reduce the manual workload for classifying articles in tasks without substantially reducing the quality of the process. To do this, we conducted experiments for three scenarios of evidence synthesis, using MEDLINE metadata on a large corpus of articles about antidepressants.

Methods

Data

We used PubMed to search MEDLINE on 9 December 2014 for articles that included in the title, abstract, or MeSH terms, the names or synonyms of one or more of the 19 antidepressants that were approved for use by the US Food and Drug Association (FDA) between 1995 and 2005. The search returned 40,098 unique articles. From this set, we selected the 22,808 articles for which the antidepressant of interest was already approved by the FDA when the article was published, and then randomly selected 1000 for inclusion in the study. We selected antidepressants for a study of author influence in postapproval opinion/commentary.

Two investigators (AD and DA) classified each article as one of eight article types: (1) systematic review; (2) non-systematic review and meta-analysis; (3) guideline; (4) randomised controlled trial; (5) other clinical study (e.g. non-randomised trial, cost-benefit analysis); (6) case study; (7) non-clinical study (animal models, chemistry for synthesis, testing, or where antidepressants are not the primary topic); and (8) comment or opinion piece. Agreement between the two investigators was 90% (Cohen's kappa = 0.87) and disagreements were resolved by discussion.

Specific characteristics (metadata) were abstracted from the articles to form the set of potential features, which are used as the basis for training the machine learning classifiers. These metadata included article titles and abstracts, MeSH terms, and publication types assigned in MEDLINE. For titles and abstracts, each word with more than three letters was extracted and binary features created to represent their presence or absence in each article. MeSH terms and publication types were used to create binary features without change. No other pre-processing methods (such as stemming or the use of stop words) were applied to the metadata prior to their use in the classifier training. The total number of features that could be used to train the classifiers was 5,606.

Three scenarios were created as examples of evidence review, synthesis, and surveillance tasks that might benefit from automation. In Scenario 1, the aim was to find all clinical trials for use in a systematic review (4 and 5, above). In

Scenario 2, the aim was to identify all randomised controlled trials for inclusion in a meta-analysis (4, above). In Scenario 3, the aim was to find only opinion pieces, commentaries, and non-systematic reviews (2 and 8, above) for examining the distribution of contributions by individual authors.

The active learning process

We defined the ordered set of articles that the user is asked to label by the learner as the *labelling queue*. The unique feature of the active learning process is that the learner iteratively trains new classifiers each time it receives an additional label from the user, and uses the resulting information to determine the order of the labelling queue.

The aim of the learner is to minimise the length of the labelling queue by converging more quickly on a classifier that is able to exceed the performance requirements.

The proposed process for applying active learning to this task includes two phases (an alternative to a previous approach [11]): the first is for when there are too few examples in each class to examine the distribution of features across the two classes and identify meaningful features (Phase I); and the second when a new classifier is trained in each step and used to select the next article to place in the labelling queue (Phase II).

Phase I

In Phase I, the issue is that there is not enough information available for the learner to know enough about the distribution of features across relevant/irrelevant articles, and thus not enough identifiable features capable of discriminating between the two classes to effectively construct a classifier.

A simple solution in this stage is to progress at random until enough useful information is available for the active learning approach. To do this, we take advantage of the statistical distribution of features among known articles. The user is asked to label articles selected at random until there are a minimum of five features that exhibit a significant difference ($p<0.05$ in a Fisher's exact test) between the classes. These features then become available for the classifiers constructed in the second phase.

Alternative methods for finding useful articles at this stage involve clustering the articles based on the distribution of features, without knowing to which class any of the articles belong [15]. We did not consider these alternatives in this study but these could reduce the workload in Phase I.

Phase II

Phase II is the active learning phase. In each round, a new classifier is trained using the labels from the labelling queue, and the information produced by applying the new classifier to the pool of remaining unlabelled articles is used to determine the next article to be labelled by the user.

For selecting useful features, we applied a simple statistical method in which features from all labelled articles (so far) are compared across the two classes (either relevant or irrelevant articles). In the statistical testing, Fisher's exact tests were applied to each feature and those with the lowest p-values were then included as features to train the classifiers. In this study, we chose to select the features that remained after a Bonferroni correction was applied, or the five features with the lowest p-values, whichever was larger.

We used support vector machines as the machine learning algorithm in these experiments, as it is appropriate for tasks such as document classification [16]. The support vector machines were constructed using linear kernels and a least squares method. To apply the active learning approach to support vector machines, the learner selects the unlabelled article that is closest to the hyperplane found to best separate the relevant and irrelevant articles during training, and passes that article to the user for labelling [12, 17].

Note that we only considered one approach for feature selection, one type of machine learning algorithm, and applied the rules consistently across all simulations. Alternative choices for feature selection and for classifiers could have affected the performance of the active learning and passive learning approaches in different ways.

Analysis

We evaluated the active learning process by estimating the risk of not achieving a pre-specified performance for each number of labelled articles. The pre-specified performance criteria were 95% recall (the percentage of relevant articles that were identified), and 90% precision (the percentage of identified articles that were relevant). Using these measures, we compared the results of the active learning simulations to a passive learning baseline, in which the articles labelled by the user are selected at random from the pool of all articles. This is equivalent to a process that continues with Phase I and never progresses to Phase II.

To estimate the risk of imperfect recall at a given labelling queue length, we ran repeated simulations to determine how many articles would need to be labelled by the user before a classifier with 95% recall and 90% precision was trained. In each case, 500 articles were selected (by stratified random sampling) for training and the remaining 500 were used as a holdout test set (which differs from a previous approach [11]). The performance results were determined by applying the classifer to the holdout set. For each of the three scenarios, we ran 1000 simulations for the passive learning baseline, re-sampling 500 articles each time.

The features that were most often used to train the classifiers that first reached 95% recall and 90% precision were reported in the active learning process as 'positive' features if they were more often present in the relevant articles, and 'negative' features otherwise.

We also examined how the process might work in practice, by conducting simulations in which the user labels 100 articles by active learning or the passive learning baseline. In these experiments, we simulated the approach 1000 times using 500 articles, but we determined the performance by testing it using the 500 articles (labelled and unlabelled) to find out if labelling 20% of articles would ensure a reliable classifier.

Results

Non-clinical studies made up the greatest proportion in the sample of 1000 articles, followed by other clinical studies, randomised controlled trials, case studies and non-systematic reviews (Table 1).

Table 1– Distribution of study types

Article Type	Frequency	Proportion
Non-clinical study	410	41%
Other clinical study	201	20%
Randomised controlled trial	130	13%
Case study	105	10%
Non-systematic review	101	10%
Systematic review	30	3.0%
Opinion piece/commentary	22	2.2%
Guideline	1	0.1%
Total	1000	100%

Scenario 1: clinical studies for use in systematic reviews

In Scenario 1, the task was to identify the 331 randomised controlled trials and other clinical studies (4 and 5, above). Applying the active learning process, the median number of articles labelled by the user when the classifier first exceeded 95% recall and 90% precision was 108 (IQR 78-146). To reach the same level of performance, the passive learning process required a median of 366 articles (IQR 284-460). This corresponds to a workload reduction of 70% in the number of labelled articles required to train a classifier (Figure 1). The results also show that for a small proportion of active learning simulations, the classifier never reached 95% recall and 90% precision (even after the user had labelled 200 articles), while for the passive learning simulations, the risk of training a poor classifier for unseen articles remained even after the user had labelled the entire training set of 500 articles.

The positive features most commonly included in the final classifiers generated by the active learning process included the MeSH terms "female" (97% of final classifiers) and "adult" (96%), the publication types "Randomized Controlled Trial" (99%) and "Clinical Trial" (97%), and abstract words "study" (70%) and "patients" (47%). Negative features included MeSH terms "Animals" (100%) or "rats" (49%), and publication type "Review" (94%) or "Case Reports" (86%).

To examine how the active learning process might work in practice, we measured the performance of the classifiers after the user had labelled 100 articles. The performance is considered *in sample*, measuring the recall, precision, and F_1-score of the 500 sampled articles including those that were already labelled (as existing methods have done [11]). The active learning process produced a median recall of 93%, median precision 96%, and median F_1-score 0.94. In the passive learning process, the median recall was 90%, median precision 90%, and median F_1-score 0.90 (Table 2). The differences in recall, precision, and F_1-score were significant ($p<0.001$) under a two sample Kolmogorov-Smirnov test.

Scenario 2: randomised controlled trials for meta-analyses

In Scenario 2, the median number of articles labelled in the passive learning process was 28 (IQR 22-38) compared to 24 (IQR 20-30) in the active learning process, representing a 14% reduction in workload (Figure 2). The results likely reflect the standardised ways in which randomised controlled trials are published, rather than the unbalanced nature of the dataset (130 relevant articles). Among the positive features that were most often used by the classifiers in the active learning process was the publication types "Randomized Controlled Trial" (99%), abstract terms "blind" (64%), "placebo" (62%), "double" (60%), and "week" (21%), and the MeSH terms "DoubleBlind_Method" (61%) and "Adult" (38%).

The marginal difference between the two approaches is reflected in the results of the practical test after the user has labelled 100 articles (Table 2), where both active and passive methods produce similar results. The differences in recall, precision, and F_1-score were significant ($p<0.001$).

Scenario 3: opinion pieces and non-systematic reviews for a task in pharmacosurveillance

In Scenario 3, the median number of articles labelled in the passive learning process was 42 (IQR 30-58) and in the active learning process 52 (IQR 37-79). This represents a 19% workload reduction in the number of training instances required (Figure 3). The results in Scenario 3 also show that a small proportion of the passive learning classifiers never reached the pre-specified stopping criteria, while the risk was minimal in the active learning process after 150 articles had been labelled. The positive features that were most often used by the classifiers in this scenario were the abstract words "therapy" (25%), "trials" (21%), "agents" (23%), "effective" (17%), and the publication type "Review" (95%). The negative features included abstract words "were" (48%) and "study" (27%), and the MeSH term "Male" (34%).

Reflecting the small gap between the passive and active learning processes, the differences in performance after the user labelled 100 articles were also relatively small (Table 2). The differences in recall, precision, and F_1-score were significant ($p<0.001$).

Discussion

We applied an active learning method to the article classification task, demonstrating that the approach can reduce the need for training instances without sacrificing recall in some scenarios. The results showed a reduction of 70%, 14%, and 19% in the number of training instances required to produce 95% recall and 90% accuracy in three evidence synthesis scenarios. These results suggest that active learning may be a feasible solution for article classification in some circumstances.

In previous methods for classifying articles in MEDLINE that did not employ machine learning methods, researchers analytically derived general seearch terms by examining very large numbers of initial articles [1-8]. These methods were generally unable to identify every relevant article, and recall could only be increased by sacrificing precision, often resulting in article lists in which fewer than half of the articles returned were relevant. As a result, extensive manual review would be required in a second stage of screening. It is likely that the active learning process presented here would improve on these approaches because it uses fewer labels to provide a low risk of missing a relevant study without sacrificing precision.

Machine learning approaches used to classify articles from MEDLINE and other bibliographic databases have been proposed for different purposes [10, 18], and active learning has been proposed for identifying relevant articles to include in systematic reviews [11]. In one example, authors used 10,000 articles as a training set, achieving 73.7% precision and 61.5% recall when identifying articles that were scientifically rigorous [9]. In another, the aim was not to label studies, but rather to order the returned documents so that the most relevant articles were listed first [19]. In the study that applied active learning, the performance of the method was determined by describing a measure of workload reduction, and the results indicated the potential for a 40-50% reduction without sacrificing perfect recall [11].

Another group of studies considers a more general task: the automatic assignment of MeSH labels to articles [20-25]. This is similar to the tasks we considered here because an accurate mapping of MeSH labels to articles could be used to replace or complement a context-specific screening of article types for inclusion in an evidence synthesis task.

The main contribution present in this study is the application of the active learning approach to article classification for evidence synthesis tasks, and an evaluation of the approach using a holdout set, examining the risk of not meeting pre-defined performance criteria for a given number of labellings. Compared to other applications of machine learning, our approach considers a relatively simple problem with binary classification by document type. However, it would be simple to extend the approach to consider more complex screening requirements where only specific study designs were relevant (e.g. specific comparators or outcome measures). Our study is also relatively simple because it considers one form of feature construction (no stemming, stop words, or n-grams), only one type of machine learning algorithm (support vector machines, no stacking or boosting), and a simple method for selecting features (selecting from a list ranked by p-values). The approach may be improved by introducing more sophisticated machine learning methods.

The differences between the three scenarios suggest that class imbalance (for example, where very few articles are relevant), and the context of the task (which influences the features that may be suitable) may both influence the length of the labelling queue required to produce high enough levels of recall and precision to make the approach worthwhile. This means that tasks aimed at identifying rare article groups may benefit least from the active learning approach but this is speculation because we considered only one scenario in which the classes were heavily imbalanced. However, identifying rare types of articles using the active learning approach has been considered in depth elsewhere [17], warranting further investigation.

Impossible guarantees and empirical estimates of risk

Tasks in evidence synthesis often require 100% recall in screening tasks [26], so it is worth considering whether an automated method can be developed to guarantee perfect recall. In inductive learning, the user and the learner are unable to calculate how well the trained classifiers will perform on unseen examples. This means that although we were able to stop the simulations when the classifier met the pre-specified performance criteria in the experiments here, this is not possible in practice.

This problem is exacerbated by the variability in the classifiers being produced using both passive and active learning within and across the scenarios. This means that the number of articles that need to be labelled by the user to meet a specific risk level may vary for different tasks. While the risk of missing relevant articles is reduced by the active learning process, the variability suggests that we do not yet have a way to (analytically or empirically) determine how many articles need to be labelled to guarantee an acceptable level of risk.

Limitations

We used only one type of classifier and one method for selecting and constructing features. While support vector machines are appropriate for tasks with a large number of features and document classification tasks in particular, other classifiers and methods for selecting features could affect the results in unexpected ways. Equally, the stopping criteria for Phase I and the final performance criteria that we reported on could have been chosen differently, and these choices could also affect the results.

We examined only one class of clinical interventions (antidepressants), and three relatively simple scenarios in

evidence synthesis. While it would be reasonable to expect that other drug classes and conditions would have similar distributions for article types and produce the same levels of performance, this may not hold for atypical interventions or conditions. Specific search queries aimed at identifying studies that meet specific design specifications may not produce the same results. For example, it may be more difficult to construct a classifier that can separate from all articles those that report on clinical trials comparing two specific interventions and report a specific measurable outcome. Other than issues with class imbalance for cases where there are very few relevant articles, the approach is general so we have no reasons to expect that the method would perform any differently in these cases.

Conclusion

In this study, we considered the problem of article classification as a shared task between a (human) user and a (machine) learner. Active learning may provide the potential to reduce the manual effort required to classify articles for context-specific tasks in evidence synthesis without reducing the performance. However, variability in the performance of classifiers within and across the scenarios suggests that we do not yet have a way to both ensure that no relevant articles are missed and substantially reduce the workload required to screen documents for inclusion in a study.

[c] *Department of Pediatrics, School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile*

Abstract

Electronic health records (EHRs) can produce significant disruption when first implemented. Successful implementations depend on the availability of technical and clinical support. We present a description of the frequency and types of issues raised during the first 12 months after the implementation of an EHR at a teaching hospital in Santiago, Chile.

Keywords:
Electronic health records; Emergency department.

Introduction

Electronic health records (EHRs) are information systems that produce significant impacts on usual clinical and administrative workflows, affecting users as well as clinical and administrative systems [1]. Although significant planning and preparation happens before they go live, EHRs produce many issues during the initial go-live and during the weeks and months following the initial date of full operation. This study sought to characterize the frequency and type of issues raised to the local help desk during the first year after the go-live of a new emergency department EHR.

Materials and Methods

This study was conducted in the Emergency Department (ED) of an urban teaching hospital in Santiago, Chile. This ED takes care of an average of 220 patients a day. Before the EHR the department used a paper medical record and paper medical orders; clinicians had access to radiology and laboratory informatin systems. The implemented system included full patient documentation and electronic orders and prescriptions.

The implementation team included experts that provided on-site, 24/7 support to clinical and administrative personnel. These professionals documented and notified issues and created help desk tickets using a smartphone application. Every issue was classified as (a) user training (b) clinical contents (c) vendor issues (d) local Information Technology (IT) team issues (e) Hardware issues and (f) User suggestions. We provide a description of the frequency and type of issues raised during the first 12 months after the ED EHR go live.

Results

The EHR went live on February 13, 2013. During the first 12 months of operation, 3372 tickets were raised by users working at the Emergency Department. As expected, a large proportion of issues were raised during the initial months of operation, with 64% of them raised in the initial 6 months. In addition to decreasing with time, we also observed a change in the distribution of types of issues. The distribution is described in Figure 1.

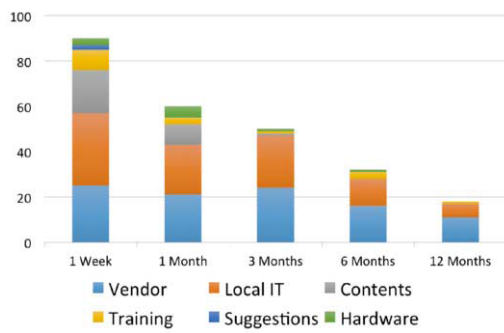

Figure 1- Frequency and distribution of EMR implementation issues (7-day periods at different times after the initial go-live)

All issues decreased their frequency over time but issues related to user training, clinical contents and hardware decreased the most.

Conclusion

As expected, most help desk issues decreased with time; however, issues related to the local IT team—such as internet connectivity, server uptime—and the EHR vendor were still present at 12 months of operation. These findings might suggest that implementation teams should carefully consider the amount of support needed from their vendors and local IT teams.

The e-NutriHS: a web-based system for a Brazilian cohort study

Luciana D. Folchetti[1], Isis T. da Silva[1], Bianca de Almeida Pititto[1] and Sandra R. G. Ferreira[1]

[1]*Department of Nutrition, School of Public Health, University of Sao Paulo, SP, Brazil*

Abstract

The e-NutriHS is a web-based system developed to gather online information on health of a cohort of college students and graduates in nutrition. It consists of six validated and internationally recognized questionnaires regarding demographic and socioeconomic data, dietary habits, physical activity level, alcohol and tobacco use, anti-fat attitudes and personal and family histories. Our software and respective database is hosted in the School of Public Health server and is based on free programming languages. An e-NutriHS prototype was created preceding online deployment. An improved version of the website was released based on 20 volunteers' opinions. A total of 503 users were registered. Considering that web-based systems produce reliable data, are easy to use, less costly and are less time-consuming, we conclude that our experience deserves to be shared, particularly with middle income economy countries.

Keywords:
e-Health, Web-based system, Cohort study, Nutrition.

Introduction

In recent years, the use of the Internet, in particular for healthcare information provision, is markedly increasing. In light of this growth, researchers of health sciences have invested in learning how to use the Web for data collection and reporting. Research studies in epidemiology are often conducted with hundreds or thousands participants, followed for long periods of time. The development of web-based online self-administered systems employing validated health-related surveys is much warranted. Such systems to obtain data related to health would be particularly important in developing countries where resources for researches are limited.

Materials and Methods

The Nutritionist Health Study (NutriHS) was conceived in 2013 by our research group from the School of Public Health of the University of São Paulo (USP), Brazil. The NutriHS is a cohort study mainly involving students and some graduates of Nutrition Graduation Courses from universities located in the State of Sao Paulo. For this first phase, launched in 2014, participants are being invited to participate in the study in which health-related data will be collected at a 3-year interval. The ethical committee at the School of Public Health of USP approved this study. A web-based system was developed to gather information online for this specific subset of the Brazilian population, the e-NutriHS.

The e-NutriHS website is based on free programming languages and with the University of São Paulo Informatics Center support, which hosted the website and respective database in the School of Public Health server (http://www.fsp.usp.br/nutrihs/index.html). For its design, the colors were carefully selected and ease-of-use was frequently reviewed until a user-friendly version of the website was obtained. A logotype was created, reinforcing the impact of increasing knowledge about nutrition on health. In addition to registration data, the e-NutriHS includes six validated and internationally recognized questionnaires regarding demographic and socioeconomic data, dietary habits, physical activity level, alcohol and tobacco use, anti-fat attitudes and personal and family histories. The length of each questionnaire page was defined based on a comfortable time for completion.

Preceding online deployment of the website for NuthiHS users, a prototype of e-NutriHS was created and hosted on a temporary url. 20 volunteers and graduates from the School of Public Health aged 25 to 60 years old and who have worked in the health area were invited to test the system and to check its ease-of-use, data entry and website design.

Results

The volunteers considered the website attractive, made favourable comments about the colours used and the interactive elements and suggested no change, after fulfilled the web-based questionnaires. An improved version of website was released based on the volunteers' opinions.

In March 2014, NutriHS participants have started to use the online web-based system. A total of 503 users were registered: 459 college students and 44 graduates. Participants were predominantly female (93%) which was expected since the majority of nutrition students are women. The mean age of the sample was 23.8 (SD 6.6) years; 63.5% were white and 84.6% were single. Preliminary lifestyle data are available, allowing for comparisons of students' profile at the beginning and end of the course. These conditions are in contrast with the nutritional epidemiological studies, which require a long period to get results.

Conclusions

Preliminary findings suggest that the feasibility of e-NutriHS may be useful to obtain data for epidemiological studies, accelerate data gathering, minimize duplicity of information and has potential to produce reliable data and identify health disorders.

Problem Oriented Medical Record: Characterizing the Use of the Problem List at Hospital Italiano de Buenos Aires

Mariano Franco[a], Maria Victoria Giussi Bordoni[a], Carlos Otero[a], Mariana Clara Landoni[a], Sonia Benitez[a], Damian Borbolla[a], Daniel Luna[a]

[a] *Health Informatics Department, Hospital Italiano de Buenos Aires*

Abstract

Problem oriented medical record (POMR) was born in late sixties. Expecting an ordered, complete and updated medical record were some of the goals of its founder. Several healthcare institutions have included problem list into their clinical records but some concerns have been reported. These concerns are in reference to their voluminosity, incompleteness and outdatedness. This study attempts to understand how healthcare professionals are using the problem list at Hospital Italiano de Buenos Aires (HIBA). We believe it is essential to understand the local reality applied to our own applications and cultural instances of documentation. This report is the basis from which several improvements could be made in order to meet the goals of Weed´s proposal.

Keywords:

Problem Oriented Medical Record; Problem List; Electronic Health Records.

Introduction

The Problem List was originally proposed by Lawrence Weed in the sixties as part of his recommendation for a POMR. The arrival of Electronic Health Records (EHRs) has suggested that it is possible to have better problem lists. Healthcare professionals at HIBA have used an electronic POMR since 1998. This paper attempts to have an understanding of the use of the problem list by professionals at HIBA as part of a plan for improvement of this instrument.

Methods

HIBA is a non-profit health care academic center. It has implemented an in-house Healthcare Information System (HIS). The hospital has an insurance plan (Plan de Salud - PS) with 150,000 members. The EHR is a fully-implemented web based, problem oriented, patient centered record with customized functionalities depending on the level of care (outpatient, inpatient, emergency care and home care). We conducted a retrospective cohort e analysis. The cohort included all new problems recorded from January 1st 2012 to December 31st 2013. A secondary de-identified database administered by the area of Biostatistics and Business Intelligence from HIBA´s Department of Health Informatics was consulted for this study. For the analysis of the problem list, the following criterion was agreed upon: all problems in all settings were taken into the sampling.

Results

During the period, there was a total of 2,478,545 new problems. Of these, 42.47 % were associated with at least one medical note. An average of 5.45 problems per patient was calculated. 35.6% of the total sample were created in the outpatient setting, 11.9% in inpatient hospitalization area, and 52.5% in the emergency. Regarding the status of problems, 96.87% were active, 0.70% problems were passive, and 2.12% problems were resolved. Grouping the problems studied by year, and day of charge, we found no significant differences. The twenty most common problems accounted for 30% of all problems. Among these, the 3 most used were fever, health check and malaise. From the top twenty problems, 38% were general symptoms or usual care situations, 23% respiratory diseases, and 39% represented other organs or systems. Of all newly created problems, 73% belonged to patients covered by affiliated insurers, corresponding to 34% of all visits in the period under study. The remaining new problems were generated during visits covered by PS. By analyzing the problems by age, the first segment of 0-5 years old had the largest proportion.

Conclusion

The first step to understand the difficulties is to determine how problem list is used. We conducted an analysis of our POMRs as a basis to generate our own strategies to improve their use, and that goes beyond the implementation of guidelines and institutional policies. Considering the difference in problems creation in the different age groups, we believe that this variability is because the problem list is created in our system once in a lifetime and it is reused for each query. Regarding the most frequent diagnoses, it is not uncommon that most of these instances are due to usual care or general pathologies. In this sense, we expected that the 20 most common problems covered a percentage higher than 30% that we found. We believe this could be due to the large granularity or level of detail that our EHR allows to incorporate. This generates a greater dispersion in the use of problems.

Secretaries' role in EHR Documentation and the Implications of Establishing a Structured EHR System

Monika Alise Johansen[a,b], Åse-Merete Pedersen[a], Gunnar Ellingsen[b]

[a] *Norwegian Centre for Integrated Care and Telemedicine, University Hospital of North Norway, Tromsø, Norway*
[b] *Telemedicine and e-Health Research Group, Arctic University of Norway, Tromsø, Norway*

Abstract

Secretaries play an important quality assurance role in today's medical record production. This study aimed to identify quality assurance tasks that a future system cannot easily compensate for when developing a new structured EHR in which the physicians do the writing themselves. The study identified two tasks, which we suggest should also be performed by secretaries in the future.

Keywords:
Electronic health records; structured EHR; dictation

Introduction

Dictation dominates today's medical record production [1]. The introduction of highly structured electronic health records (EHR) implies that physicians have to record the data in the EHR system — that is, write the patient documentation themselves.

Speed, accuracy and completeness improve when doctors use structured templates instead of dictation [2]. Doctors who write patient journals themselves seem to write more briefly and in a way that makes the documentation more readable [3]. A large-scale study in primary care setting showed improved quality of patient care when physicians entered information directly into the structured records [4]. In addition, the documentation is available much earlier - half an hour after the consultation - compared to 374 hours later if the journal note is dictated [5].

However, doctors' change of work practice from dictating to recording may overlook the fact that secretaries play an important quality assurance role in today's EHR production [1]. This study aimed to investigate secretaries' quality assurance role and to identify work that cannot be easily compensated for when designing and establishing a new structured EHR system in which the physicians write the patient documentation themselves.

Methods

Both qualitative and quantitative methods were applied. For the qualitative research, an interpretative study approach was used and data were collected through informal discussions and focus group interviews. In addition, secretaries were asked to fill out one anonymised survey per day, over two consecutive weeks to record their quality assurance work.

Results

The results revealed that secretaries perform numerous quality assurance tasks. Two of the quality assurance tasks were regarded as especially challenging for the future EHR system to compensate for. These work tasks were reported on 28 of the survey forms, representing an equal number of workdays. The first task was to correct the instances in which the same patients had been registered twice or more in the EHR; this issue was corrected 118 times. In addition, the secretaries made 169 corrections due to incorrect patient names or other incorrect essential patient information. This demonstrates that during 28 days of work, each secretary conducted an average of more than 10 very important corrections that could be challenging for the future system to compensate for.

Discussion and Conclusion

Today's secretaries perform numerous important corrections and quality assurance tasks in EHR production. When designing and developing the new structured EHR system, as many as possible of these tasks need to be compensated for by the system. However, to support doctors, we suggest that the following two quality assurance tasks should also be performed by secretaries in the future, as these tasks are very time-consuming and cannot be easily compensated for in the new structured EHR system. These tasks are: correcting the patients' registration and correcting important patient information when mistakes have been identified.

Development of Markup Language for Medical Record Charting: A Charting Language

Won-Mo Jung[a], Younbyoung Chae[a], Bo-Hyoung Jang[b]

[a] *Acupuncture and Meridian Science Research Center, College of Korean Medicine, Kyung Hee University*
[b] *Department of Preventive Medicine, College of Korean Medicine, Kyung Hee University*

Abstract

Nowadays a lot of trials for collecting electronic medical records (EMRs) exist. However, structuring data format for EMR is an especially labour-intensive task for practitioners. Here we propose a new mark-up language for medical record charting (called Charting Language), which borrows useful properties from programming languages. Thus, with Charting Language, the text data described in dynamic situation can be easily used to extract information.

Keywords:
Electronic Medical Record; Medical Language Processing.

Introduction

In these days, organizing collection of electronic medical records (EMRs) is regarded as fruitful attempts and many trials have been made in various ways [1]. Most of the platforms being used to collect medical records require practitioners to fill structured data forms. Yet, it might be too strict and rigid form for real clinical situations where dynamic interaction between practitioners and patients exists. Whereas, when the practitioners describe medical records in free-text form, it is difficult to extract data for secondary analysis. Thus, trade-off exists between structured and free-text EMR system. [2] Standardized information model might be one of solutions to the problem, such as HL7 CDA and CCR of ASTM International. The standards are useful references for the process of developing interoperable EMR systems, but the standards do not consider the situation when the individual practitioners construct EMR data directly using the standards [3]. Here, we propose a mark-up language for charting medical record (called Charting Language) by which individual practitioner constructs their EMR structure without constraints and with ease at each treatment.

Methods

The charting language we propose borrows useful properties from programming languages. The charting language is a mark-up language with easy and simple syntax to describe medical records by practitioners in clinical situations. We defined a language grammar that has a hierarchical structure of compound literals (object or section) consisting of primitive literals. The main primitive literal is a medical term that can be imported from a shared library. Because the medical records written by Charting Language has specifically defined syntax and uses medical terms with semantic interoperability, the medical records can be extracted for secondary use of data, like compiling process in the normal programming language. Additionally, within a defined syntax, it provides the capacity to write down medical records without the constraint of the structure within a defined language.

Results

Figure 1 – The abstract syntax and an example.

Syntax of the language was defined in XML format following tmLanguage rule used in popular text editor softwares. For functional convenience, additional plug-ins and snippets were also implemented to help efficient documenting.

Using Electronic Medical Record Data to Improve HIV Patient Monitoring, Clinical Decision-Making, and Quality Improvement: Lessons from Rwanda

Nadine Karema[a], Anatole Manzi[a], Erick Gaju[b], Michèle Kayiganwa[b], Eric Remera[c], Alphonse Nshimyiryo[a], Gad Niyibizi[c], Adeline Dukuze[c], Neil Gupta[a, d], Cheryl Amoroso[a]

[a]Partners In Health/Inshuti Mu Buzima, Rwanda
[b]Rwanda Ministry of Health
[c]Rwanda Biomedical Center
[d]Division of Global Health Equity, Brigham and Women's Hospital, Boston, USA

Abstract

In developing countries, clinical guidelines and patient follow-up are primarily paper-based. We describe the use of Electronic Medical Record data for evidence-based clinical decisions and improved HIV patients monitoring in rural Rwanda.

Keywords:
Electronic Medical Records; HIV; Viral load.

Introduction

In 2006 and 2010, two innovative systems were respectively implemented in Rwanda through the joint effort of Partners in Health (PIH) and the Ministry of Health (MOH): the Electronic Medical Record (EMR) system, and the Mentorship, Enhanced Supervision and Quality Improvement Program (MESH-QI). MESH-QI mentors used EMR as a detection and monitoring tool to identify and design QI interventions.

Methods

A QI intervention focused on clinical decisions and HIV patients monitoring was conducted by 2 nurse mentors in 14 health facilities of Kirehe district. The aim was to improve rates of eligible HIV patients tested for viral load (VL) from 2.8% to at least 50% within 3 months (Nov 2012-Feb 2013). The number of each facility patients due for VL testing, and proportions of those with test results were aggregated into EMR reports reviewed and discussed during data sharing meetings held with health facilities leaders. EMR was used to track site performance, and Chi-squared test was used to measure differences pre- and post-intervention.

Results

Figure 1 reports changes in VL testing before intervention [N = 2223 (children = 135 & adult = 2088)] and after intervention [N = 2387 (children = 138 & adult = 2249)].

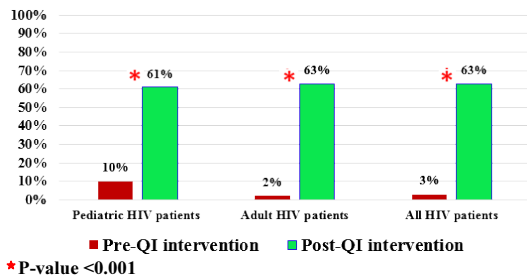

Figure 1- Changes in viral load testing

Conclusion

Use of EMR data may contribute to improve patient monitoring and evidence-based clinical decisions. These findings suggest EMR as a potential source and reference for HIV clinical record keeping, reporting, decision-making, and data-driven QI.

Restructuring an EHR system and the Medical Markup Language (MML) standard to improve interoperability by archetype technology

Shinji Kobayashi[a], Naoto Kume[a], Hiroyuki Yoshihara[b]

[a] *The EHR research unit, Kyoto University, Kyoto, Japan*
[b] *Miyazaki University Hospital, Miyazaki, Japan*

Abstract

In 2001, we developed an EHR system for regional healthcare information inter-exchange and to provide individual patient data to patients. This system was adopted in three regions in Japan. We also developed a Medical Markup Language (MML) standard for inter- and intra-hospital communications.

The system was built on a legacy platform, however, and had not been appropriately maintained or updated to meet clinical requirements. To improve future maintenance costs, we reconstructed the EHR system using archetype technology on the Ruby on Rails platform, and generated MML equivalent forms from archetypes. The system was deployed as a cloud-based system for preliminary use as a regional EHR. The system now has the capability to catch up with new requirements, maintaining semantic interoperability with archetype technology. It is also more flexible than the legacy EHR system.

***Key words**:* archetype, EHR, ISO 13606, MML, openEHR

Introduction

In the Dolphin project, we developed an EHR system for regional health providers to share clinical records and provide individual patient data to patients [1]. We also developed an XML-based standard called Medical Markup Language (MML) to share clinical data within and among hospitals [2]. This EHR system has been working successfully with more than 6000 patients in three regions in Japan. However, this system was not sufficiently maintained or updated because it was built on a legacy web framework, written in the now old-fashioned Perl language. Therefore, we decided to reconstruct the EHR system using common clinical models designed on the ISO 13606 standard with the openEHR specification [3] to improve flexibility.

Methods

We adopted Ruby on Rails as a web framework and a Ruby implementation of the openEHR specification [4]. We redesigned web forms and MML equivalent messages based on clinical concepts involving archetypes in the openEHR clinical knowledge manager (CKM) (http://www.openehr.org/ckm/), with or without modification, plus newly created archetypes. We designed archetypes using the Ocean Archetype Editor and redesigned forms and messages using the Ocean Template Designer.

Results

All of the EHR data components were redesigned using archetypes and are now composed of equivalent templates meeting openEHR specifications. MML messages were generated from archetype components. The web system was implemented for these clinical models with Ruby on Rails and a PostgreSQL database. After functional review, we deployed the system on a cloud platform for preliminary use, for EHR management.

Discussion

Once an EHR system is deployed, it needs maintaining and updating. Moreover, progress in medical knowledge can make systems obsolete. However, archetype technology makes it possible to apply future-proof clinical concepts to construct an EHR system. The restructured EHR system also has improved flexibility for revisions.

Conclusion

EHR systems inevitably need revising. The findings from this work suggest that archetype technology can improve the flexibility of EHR systems.

Validation for Accuracy of Cancer Diagnosis in Electronic Medical Records Using a Text Mining Method

Yura Lee[a], Soo-Yong Shin[a], Sung-Min Ahn[a,b], Jae-Ho Lee[a,c], Woo-Sung Kim[a,d]

[a]*Department of Biomedical Informatics, Asan Medical Center,*
[b]*Department of Oncology, Asan Medical Center,*
[c]*Department of Emergency Medicine, Asan Medical Center,*
[d]*Department of Pulmonology and Critical Care, Asan Medical Center, Seoul, Republic of Korea*

Abstract

To validate the accuracy of data in electronic medical record, we compared cancer diagnosis and key words in pathologic reports of cancer patients in a tertiary hospital, using text mining method. We investigated in fourteen kinds of cancers that had highest incidence rates in Korea. Approximately two-third (71.0%) of total patients had right match in cancer diagnosis with pathologic report. The ratio of concurrence was the highest (86.3%) in thyroid cancer patients, however, the ratio was the lowest (49.9%) in liver cancer patients. To prevent the errors in data input, a systematic alarm and feedback to clinicians should be required.

Keywords:

Cancer diagnosis; Data quality; Text mining; Data validation

Introduction

Electronic medical record (EMR) system has propagated rapidly, and the size of computerized medical data has been increased exponentially [1]. Accordingly, the quality of medical data has been emphasized not only for patients' safety but also for various purposes. For example, a huge amount of medical data is being managed for supervision of public health. For the convenience and the efficiency of treatment, implementation of inter-center communication via electrical health data is inevitable. In clinical research, the key of confidence of the results is proper size and quality of data.

As an indicator of medical data quality, we checked the diagnosis of cancer patients and compared with the reports of pathologic examinations. We matched the code of diagnosis, recorded based on the ICD-10, with the report of pathologic examinations, via text mining method.

Methods

Fourteen kind of malignant diseases were investigated: thyroid cancer, stomach cancer, colorectal cancer, lung cancer, liver cancer, breast cancer, prostate cancer, pancreatic cancer, bile duct cancer, non-Hodgkin's lymphoma, kidney cancer, cervical cancer, and ovarian cancer. Those cancers had highest prevalence in Korea, reported by National Cancer Information Center of Korea. We included the cancer patients' data from January 1st, 1989 to December 31st, 2013 in Asan Medical Center, Seoul, Korea.

Based on diagnosis codes (ICD-10) typed by clinicians, we categorized the patients into 14 groups of cancers. All pathologic reports of each patient were filtered out by the presence of the specific key words in the text. If there were one or more pathologic reports that contained corresponding key words with the patient's diagnosis, the patient was considered to have correct diagnosis.

Results

During the study period, 236,012 cancer patients had pathologic examination at least once. Approximately two-third of the patients were filtered as there were one or more pathologic reports that contained corresponding key words (167,530/236,012, 71.0%). In thyroid cancer patients, the correspondence of the keyword was the highest among the 14 groups of cancers (86.3%). The lowest proportion ratio of filtration was in the liver cancer group (49.9%), followed by cervical (53.8%) and ovarian cancer (62.2%).

We randomly reviewed the EMR of 100 patients in unfiltered, liver cancer group. Seventy nine of the 100 patients diagnosed liver cancer without pathologic examination. Twelve were non-liver-cancer patients with or without metastasis to liver. Seven patients were missed due to the limitation of filtering though they had proper diagnosis of liver cancer, and the rest two patients had pathologic examination at other hospital.

Conclusion

We could not condemn the one-third unfiltered diagnosis as wrong diagnosis. In liver cancer, the main diagnostic approach is made by the history of underlying liver disease and the results of imaging studies. Therefore, more research should be followed.

However, most of clinicians lack of awareness in correct data input particularly in the cancer patients with vague primary origin or tumors involved in two or more organs.

As clinical decision support systems prevent errors in medical fields, active feedback and alarm system for clinician to guide entering diagnosis may lower the error rate of medical record.

Developing an Electronic Medical Record for Interlinked Care Services in Haiti

A Marcelin[a], C Perodin[a], C Baja[a], A Bright[a], J Duperval[a], M Duplan[a], F Dérilus[a], S Duda[b], J Pape[a,c]

[a] *Groupe Haïtien d'Etude du Sarcoma de Kaposi et des Infections Opportunistes (GHESKIO),* [b] *Vanderbilt University,* [c] *Weill Medical College of Cornell University*

Abstract

A large clinical care and research organization in Haiti required an electronic medical record system (EMR) to serve the needs of its 30 interlinked clinical programs. After assessing available open source software, the local team designed and implemented a modular proprietary EMR that is improving data quality and patient care. Despite the many benefits of existing open source medical record systems, clinical centers with complex workflow patterns -- even those in resource-limited settings -- should consider developing sustainable, local systems that fit their care model.

Keywords:

Electronic Medical Records; Developing Countries; Haiti.

Introduction

GHESKIO Centers in Port-au-Prince, Haiti, is the largest HIV/AIDS care and treatment institution in the Caribbean, providing continuous medical care since 1982. GHESKIO offers more than 30 separate clinical and support programs, from HIV, tuberculosis, and cholera care to maternal and child health and sexual violence prevention. GHESKIO maintains electronic medical records for over 425,000 patients using a legacy Clipper/dBase system, but the outdated technology could not scale to meet new data collection needs.

Methods

In October 2010, the GHESKIO technical team (all Haitian) engaged all stakeholders to conduct a needs assessment for a new EMR. They identified six core requirements. The system should (1) manage patient information across a wide variety of activities and GHESKIO programs, (2) interface with existing Lab Information and Pharmacy Systems, (3) accommodate a step-wise EMR rollout with minimal disruption to ongoing clinic activities, (4) link GHESKIO's care sites across the city, and (5) allow insertion of temporary data collections to support GHESKIO's research mission. Finally, (6) the EMR must be maintainable locally by GHESKIO developers.

The team installed and evaluated open source EMRs including OpenMRS, OpenClinic, and the Haitian government's iSante EMR [1,2], but the necessary base code changes to fit GHESKIO needs broke the software upgrade path. To meet core requirements, GHESKIO decided to build an EMR. They worked with clinicians to identify key functionality, design data forms, and remove duplicate information.

Results

The GHESKIO EMR was implemented in Microsoft .NET by three full-time programmers over 18 months. The EMR went live in May 2012, with 13 of 16 modules available as of December 2014. Over 425,000 patients records were migrated and clinicians entered data at the point of care and received electronic, rather than paper, notification of lab results, which expedites patient treatment. Medical records were combined for the 1500 patients who had received care at the two GHESKIO facilities. Challenges included data migration, and training of over 90 clinicians in the use of the new EMR. The new EMR is robust in the wake of natural disasters, because data are backed up in different buildings within sites and also between sites. Data comprehensiveness improved with a 100% increase in available data fields. Providers now can code 3,959 symptoms and diagnoses mapped to ICD-10 codes and presented in user-friendly auto-complete fields, compared to the 115 pre-defined symptoms and diagnoses in the old EMR. The EMR has also facilitated the evaluation and publication of outcomes data [3-5].

Conclusion

Existing EMRs designed for resource-limited settings may not meet the needs of highly interlinked care centers with large research programs. GHESKIO's tailored EMR permits the organization to document patient care with greater precision, participate in a broader set of research studies, and improve continuity of care. This report demonstrates the feasibility of locally implementing and maintaining customized EMRs at major clinical care centers in resource-limited settings.

Applicability of different types of Patient Records for Patient Recruitment Systems

Björn Schreiweis[a], Björn Bergh[a]

[a] *Center for Information Technology and Medical Engineering, University Hospital Heidelberg, Germany*

Abstract

Patient records – types of Electronic Medical Records – are implemented to support patient recruitment. Different types of patient records have not yet been analyzed as to the number of Patient Recruitment System requirements can be found in each type of patient record. According to our analysis, personal electronic health records (PEHRs) tend to allow for most requirements to be found.

Keywords:

Clinical trials as topic, patient recruitment system, PRS, EMR, EHR, PEHR.

Introduction

The increasing availability of electronic health information has resulted in an increasing number of options for the secondary use of health information. One important secondary use is supporting patient recruitment for clinical trials. Clinical trials often fail to complete recruitment on time, inadequately obtain the correct number of recruits and/or experience budgetary problems [1]. Patient Recruitment Systems (PRSs) are used to improve patient recruitment [2]. PRSs are often integrated with Electronic Medical Records (EMRs), but have not been analyzed as to how other types of records match with the requirements of PRSs.

This work analyzes the applicability of different types of patient records for their integration with PRSs by analyzing the requirement implementation capacity of PRSs.

Methods

A requirements analysis resulting in 13 requirements of PRSs was performed; by conducting unstructured interviews and a literature review [3]. A literature search on types of patient records currently implemented was performed and resulting patient records were analyzed as to their different functionalities and operational paradigms. We found several types: EMRs as records implemented within a healthcare institution, Electronic Health Records (EHRs) as records implemented in healthcare networks (cross-institutional), EHRs for a distinct medical condition (ger: Elektronische Fallakte (EFA)), Personal Health Records (PHRs) for patients' documentation on their own medical history and Personal Electronic Health Records (PEHRs) integrating both PHR and EHR capabilities; allowing for the integration of clinical documentation from the EHR, for patients adding documentation on their own (PHR) and also for patients to control the privileges of their PEHR.

Results

We found differences in the capacity to integrate PRS with EMRs, EHRs, EFAs, PHRs and PEHRs.

Integrating PHRs with EMRs suggests 61.5% (8 of 13) of the requirements are implementable. For EHRs, PHR integration suggests 53.8% (7 of 13) of the requirements are implementable. In an EFA, 30.8% (4 of 13) of the required functionalities can be realized by integrating a PRS. Integrating a PRS with PHRs allows for 38.5% (5 of 13) of the requirements to be implemented. PEHRs are fully implementable for 84.6% (11 of 13) of the required functions. Two functions of PRSs are partly implementable in PEHRs, as patient consent can prevent physicians to be informed about contacting eligible patients because patients can choose not to inform the physician that they are eligible.

Discussion

The integration of a PRS within a PEHR environment allows for the comparison between other types of patient records on the topic of their implementation of requirements for PRSs. Data integration and use of medical information for research purposes (such as matching eligibility criteria) are fully controlled by the patient through consent management. A PRS integrated with a PEHR would be a cross-enterprise PRS, a XPRS.

Conclusion

Further research on PRS integration with PEHRs will be performed and intends to lead to architectures capable of informing how the integration of PRS with PEHRs can be achieved successfully.

Evaluating the data completeness in the Electronic Health Record after the Implementation of an Outpatient Electronic Health Record

Mauricio Soto[a], Daniel Capurro[b], Silvia Catalán[c]

[a] *Department of Family Medicine, School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile*
[b] *Department of Internal Medicine, School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile*
[c] *Department of Pediatrics, School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile*

Abstract

Electronic health records (EHRs) present an opportunity for quality improvement in health organitations, particularly at the primary health level. However, EHR implementation impacts clinical workflows, and physicians frequently prefer to document in a non-structured way, which ultimately hinders the ability to measure quality indicators. We present an assessment of data completeness—a key data quality indicator—during the first 12 months after the implementation of an EHR at a teaching outpatient center in Santiago, Chile.

Keywords:
Electronic health records, Outpatient, Data completeness.

Introduction

There is a significant gap between the data that are captured during routine clinical care and the structured data needed for secondary analyses [1]. In an attempt to assess the impact of our implementation strategy, this project sought to characterize the level of data completeness—according to our local documentation quality standard—and level of completeness of the different functionalities of the system during the first year after the go-live of the outpatient EHR.

Materials and Methods

This study was conducted in an outpatient clinic, affiliated to an urban teaching hospital in Santiago, Chile with an average of 3000 visits/month. Our implementation included strategies to increase adoption: personalization of documentation using templates, online and classroom training, on-site personal support and the use of audit and feedback based on the level of completeness of EHR use by physicians. Our EHR completeness quality standard involves the proportion of medical visits with complete documentation in all five priority areas: chief complaint, history of present illness, physical examination, clinical diagnosis, and patient suggested plan.

Results

The EHR went live on December 2013. During the first months 49.7% of all clinical encounters met the data completeness quality standard. Figure 1 describes temporal evolution during the 12 months after the implementation. Observed compliance was higher than reported by the literature. Table 1 describes completeness of each area of clinical documentation.

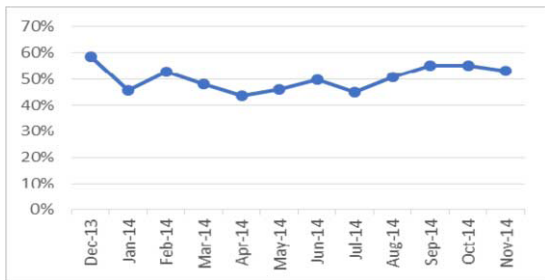

Figure 1- Quality standard compliance of data completeness during 1 year after the EHR implementation

Table 1.

Clinical Documentation Domain	Completeness	Roth 2013[2]
Chief complaint	91%	12%
History of present illness	71%	30%
Physical exam	76%	14%
Diagnosis	100%	72%
Suggested plan	73%	

Conclusions

After one year, we have observed high and stable rates of data completeness. This suggests successful adoption strategies implemented before and after implementing the new EHR.

Health Information Needs for Child-in-Care

Cori Thompson[a]

[a] *School of Health Information Science, University of Victoria, BC, Canada*

Abstract

When a child is taken into care the State is legally required to provide healthcare. Six forms were reviewed by medical care providers, foster parents and government social workers to understand their health information needs in caring and planning for child-in-care. The qualitative study used a sociotechnical systems framework and NVivo 10 for encoding. Interview findings include that the forms, if completed and available, meet most basic health information needs with additional forms used for complex health needs. The majority of participants indicate interest in electronic options. Focus groups will enable further study.

Keywords:

Foster Care; Health Record

Introduction

Children are considered vulnerable populations at risk for not having health needs met [1]. The State or Province has a duty to provide healthcare to a child- or youth-in-care (CIC) [2]. Health records tailored to CIC exist [3]. A study was conducted with medical care providers, foster parents, and social workers from a provincial social sector ministry that provides protection services to children and families. The study asked what health information the participants need to provide care to and plan for child-in-care.

Methods

Qualitative research with a sociotechnical systems (STS) framework [4] was used to understand the findings. The STS concepts include: social and technical analysis; variance control; linear / non linear tasks; blurring of roles; information sharing; coalitions; and deliberations and decisions [4]. The 19-question interview tool included reviewing six forms: newborn record, child medical record (CMR), birth family medical and social history, care plan, Looking After Children health section, and healthcare passport. The CMR was the main form studied. It is a snapshot of the overall health of the child when a child transitions (eg. into care). Participants were asked for professional opinions. Interviews were recorded, transcribed and are inductively encoded using NVivo 10 QSR.

Results

From November 2013 to 2014 thirty-three interviews were held with thirty-nine participants in six urban, rural and/or remote communities. Most interviews were conducted on site. Findings suggest the forms, when completed and available, generally work, with additional forms needed for complex care needs. The CIC health record information starts with the birth family social history and history of illness and the birth mother's pregnancy up to the CIC's health and development at age 19, including dental care and placements. At age 19 CICs have access to their information. Reunification or permanency planning goal impacts the information collection. Primary data sources, temporal dependency and some redundancy were identified between forms. Medical care providers, foster parents and government social workers may each change while the CIC is in care. The CIC may also transition in and out of care. The legal guardian role, which consents to treatment and information sharing, may transfer between biological parents and ministry. All these changes increase the system's complexity and may increase risk of record fragmentation. Missing information might include: biological parent's health information, CIC's childhood illnesses, records not gathered prior to assessment. Good communication, help with timely record collection, education, healthcare advocacy, clearer guidelines on information sharing, and funding were identified as potential enablers. The majority of participants indicate an interest in electronic options.

Conclusion

If completed and available, the six forms seem to generally meet basic information needs, with additional forms needed for complex health needs. Careful consideration needs to be given to any electronic option as technology adds complexity [5] to an already complex system. Study limitations include that one researcher conducted, transcribed, and encoded the interviews. Focus groups will enable further study.

Acknowledgments

A sincere thank you to the participants and to the individuals and organizations guiding this study.

Video Conferencing Services in Healthcare: One Communication Platform to Support All

Andrius Budrionis[a], Per Hasvold[a], Gunnar Hartvigsen[a], Johan Gustav Bellika[a]

[a]*Norwegian Centre for Integrated Care and Telemedicine, University Hospital of North Norway, Tromso, Norway*

Abstract

We present a novel approach to the design of video conferencing (VC) systems, taking advantage of recent technological achievements in web-based implementation. Delivering VC functionality as a service over the Internet opens new grounds for easier integration, support, and application in many scenarios, since hardware-agnostic ad-hoc VC connections are a feature of the proposed architecture. Validity is demonstrated through latency measures in a surgical telementoring service and comparing them to reported thresholds.

Keywords:

Telementoring; Scalable; WebRTC; Latency.

Introduction

Video conferencing (VC) is a common core technology in telemedical systems. The integration of VC into clinical workflows is associated with high complexity, which prevents exploitation of the potential in various scenarios. Platform dependency, client software installation and updates, complications in traversing complex network topologies, and firewalls are common issues which often need to be taken care of by users. The complexity of employing such systems in clinical settings, while ensuring high availability and managing maintenance costs is just one reason for the slow progress and adoption of the approach, regardless of its high potential.

The use of VC is still limited to planned meetings that are configured and tested in advance. Even the most user-friendly VC systems – like Skype, Google Hangouts, and more advanced solutions by Cisco or Polycom – require registration, software downloads, and installation. However, numerous use cases call for a more flexible and user-friendly VC interface. For instance, emergency surgical telementoring sessions, or GP-patient consultation over VC. Devices used remotely cannot be set up in advance and need to work on-the-fly.

Materials and Methods

Web Real-Time Communication (webRTC) was selected as a backbone for implementing a general purpose VC infrastructure meeting the needs of the evolving healthcare environment [1]. It aims to provide a customizable VC gateway for developing platform-agnostic clinical applications featuring low usability threshold ad-hoc connections between peers.

One-way latency of the proposed system was measured to assess compliance with the reported thresholds in surgical telementoring [2]. VC node was started on an i5 Macbook Pro (late 2013) with 8GB of RAM, and accessed from a 10.1" Asus MeMO tablet computer with 1 GB of RAM, running Android 4.2, on a dedicated network. Two light sensors connected to an Arduino circuit board registered lighting changes on the screens of the interacting peers when a white sheet of paper was put in front of the camera. The experiment was repeated under different network loads.

Results

The generic architecture in Figure 1 provided a framework for developing platform-agnostic VC services. One-way video latency measures averaged at 226.7 ms under perfect network conditions, and 325.7 and 338.7 under 0.5 MB/s and 1 MB/s data traffic respectively. The use of the service added a 133.2 ms delay to the native latency of the network.

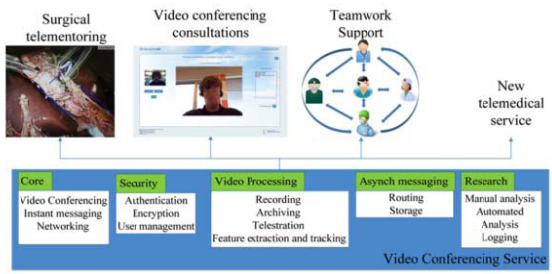

Figure 1. Generic architecture of a VC service

Conclusion

We present a generic architecture providing a secure, highly available, and easy to integrate VC channel that adds no additional maintenance and support costs to hospitals or patients. No matter what technical infrastructure lies between the two interacting parties, the only requirements for establishing the VC session is an updated web browser and an Internet connection. The feasibility of using the architecture to build clinical services was demonstrated and revealed promising results; one-way video transmission latency was acceptable in a surgical telementoring scenario. Assuming lower latency requirements in less safety-critical use cases enables easy adoption of telemedical practices in a wide spectrum of scenarios within both primary and secondary care, which are currently not supported by existing systems.

Implementation of a Teleconsultation Service in the Primary Health Care in Brazil

Rodrigo V. Andreão[a], Marcelo Q. Schimidt[b], Thiago D. Sarti[b], Solange L. Corradi[c]

[a] *Federal Institut of Espirito Santo, Vitoria, ES, Brazil*
[b] *Federal University of Espirito Santo, Vitoria, ES, Brazil*
[c] *Planning Department, Espirito Santo Secretary of Health, ES, Brazil*

Abstract

The implementation of a Teleconsultation service in the primary health care is a great challenge. This work presents the effort made in the Espirito Santo Telehealth Project to consolidate the teleconsultation service. The impact of each strategy made was evaluated in terms of the number of teleconsultations produced. The combination of periodic visits and the promotion of local workshops were responsible for a sustainable use of the service for the last six months.

Keywords:
Telehealth; Teleconsultation; Primary Health Care.

Introduction

Considering the great contrast in offering the primary health care (PHC) in Brazil, the Brazilian Telehealth Program in Espirito Santo state, is being implemented aiming at providing the increase of the resolution of most clinical cases and the reduction of the forwarding of patients at the PHC level.

The main challenge of the project is to introduce this new program in the health professional routine, covering 78 cities of the Espirito Santo state, more than two hundred of health units and thousands of health professionals.

There are many experiences in Brazil and in other countries which have approached such subject. However, our ongoing experience shows that new strategies must be taken into account in order to place the telehealth services in the routine of the health professionals.

In this work, we present our strategy during the implementation of the Telehealth Program in Espirito Santo, focusing on the Teleconsultation service. Our results, which were based on a survey answered by the health professionals, confirm the fact that there is a demand on the teleconsultation service.

Materials and Methods

The teleconsultation service consists in offering a qualified second opinion in response to the questions made by local health care provider. This second opinion is a text message made by family physicians, nurse practitioners, and others specialists with expertise in telehealth and general practice and is based on the best available scientific evidence. This kind of collaboration among health professionals takes place in a web based plateform called Salus, where the access is secure and controlled by a personal password.

The service is offered to a health unit city since it meets the following requirements: a. health secretary approval; b. health unit providing a computer connected to the internet; and c. health professionals must follow a short course on the Telehealth project and the Salus platform.

However, during the implementation of our teleconsultation service, we noticed that the requirements above were not enough to the success of the project. In fact, placing the teleconsultation service in the routine of the health professionals remains a great challenge. In order to face this, we included the following strategies: i. phone calls to the manager of the health unit and to the doctor; ii. periodic visits to the health units connected to the project; iii. local workshops exchanging experiences among health professionals; and iv. a financial support to the cities which is participating to the telehealth project.

Results and Discussion

The implementation of the teleconsultation service started on February 2012, when the first health unit was connected. We noticed that during one year and a half, the teleconsultation service did not progress enough and the number of teleconsulations did not cross 29 teleconsultations per month, produced by 19 health centers. As a consequence, we decided to telephone the managers and doctors of the PHC. After that, we detected a sudden increase of the teleconsultations up to 62 per month, produced by 32 health centers. However, the phone calls did not produce a sustainable use because the number of teleconsultations decreased one month later. In order to raise the awareness towards the teleconsulting, we promoted three other strategies, particularly local workshops exchaging experiences about the benefits of the teleconsultings and periodic visits to the health centers of telehealth. These strategies produced a sharp increase up to 124 teleconsultings/month, produced by 30 health centers, which remained sustainable for six months confirming that there is a demand to be met. We believe that repeating these strategies every year the teleconsultation service can definitly became as a part of the routine of the health professionals.

Introducing Home Blood Pressure Telemonitoring for Children with Hypertension

McKenzie Bedra, MPH, Joseph Finkelstein, MD, PhD

Johns Hopkins University School of Medicine, Baltimore, MD, USA

Abstract

The goal of this study was to introduce home blood pressure (BP) telemonitoring in children with hypertension and to assess the feasibility of this approach. Acceptance of the system was assessed by attitudinal survey and semi-structured qualitative interview. Qualitative interview results showed consistently positive comments for content, interface and process components. BP measurements obtained by self-testing were as reliable as Dinamap measurements. The home telemonitoring system was positively accepted, easy to use and found to be helpful by participants. Home-based BP telemonitoring has significant potential to improve patient-centered delivery in children with hypertension.

Keywords:

Telemonitoring, Hypertension, Children, Disease Management, Self-care

Introduction

The long-term goal of this project is to improve adherence to monitoring of blood pressure and anti-hypertensive medication, thereby decreasing hypertension-related morbidity and mortality in adulthood. To achieve this goal, this study had the following specific aims: 1) develop and evaluate patient/caretaker satisfaction with a telemonitoring system for blood pressure (BP) in children with essential hypertension, which will involve self-monitoring at home and allow prompt reciprocal exchange of medication adherence and BP measurement information between patients and health care providers; 2) evaluate the validity of BP measurements obtained during home telemonitoring by comparing results to those obtained by a trained professional; 3) determine patient adherence to BP monitoring and hypertensive medication after utilizing the home telemonitoring system in comparison to self-reported adherence prior to using the system.

Materials and Methods

The hypertension home telemonitoring system included a portable oscillometric blood pressure monitor and appropriate-sized blood pressure cuff, which was connected via a serial port to a laptop computer. The laptop allowed transmission of blood pressure and patient response data (reporting of symptoms of hypertension or hypotension, and side effects of anti-hypertensive medications) via wireless network to the medical center's secure clinical information system twice a day. The laptop computer's functions were limited so that only home blood pressure monitoring could be performed, analogous to an automated teller machine.

Results

Eight children with essential hypertension were enrolled from a pediatric nephrology clinic. The average amount of time that participants took to complete all components of the home telemonitoring system was 256 ± 125 seconds. The blood pressure symptom diary took an average of 31 ± 20 seconds, while assessment of medication side effects took an average of 33 ± 11 seconds. Self-monitoring of blood pressure took an average of 149 ± 79 seconds and completion of the hypertension education module took 43 ± 26 seconds on average. Overall, there were no significant differences noted in the measurements, however self-monitoring took approximately 55 seconds longer on average as compared to measurement with Dinamap and this difference was significant. Attitudinal survey results demonstrated that 88% of participants reported that working with the computer was not difficult, and 100% reported that the self-testing procedures, blood pressure monitor, symptom diary and medication side effect questions were not complicated. Seventy-five percent felt the self-testing procedure took little time and did not interfere with their usual activities. Sixty-three percent felt slightly to significantly safer while monitored by the home telemonitoring system and felt it was important to know that the self-testing results could be immediately reviewed in the medical center after the test. Overall, 88% would like to use the home telemonitoring system in the future. The following were typical responses that focused on content: "The symptoms that were listed in the symptom diary were helpful. They are symptoms that I actually feel," and, "I thought the education was the best part because I can learn more about high blood pressure and what symptoms I might have." Examples of responses that focused on the interface included: "I thought the home BP machine was easy to use, and the instructions were very clear."

Discussion

Home-based BP telemonitoring has significant potential to improve patient-centered delivery in children with hypertension. Patients and caregivers provided valuable feedback which should be addressed in future generations of the system. Next steps should include definitive evaluation using randomized study design to evaluate impact of home-based telemonitoring on clinical outcomes in children with hypertension.

Acknowledgments

We are very thankful to Dr. Cozumel Pruette for providing access to the study subjects and useful comments on clinical aspects of the study protocol.

Providers Expectations on Telemedicine: A Qualitative Research in a Large Healthcare Network of Latin America

Giussi Bordoni MV, Plazzotta F, Sommer J, Benítez S, García G, Luna D, González B De Quirós F

Health Informatics Department, Hospital Italiano de Buenos Aires

Abstract

The benefits of Telemedicine make it a viable, reliable and useful discipline for dispensing health care. This qualitative study is aimed to understand the expectations, opinions and previous knowledge of the professionals about telemedicine at the Hospital Italiano de Buenos Aires. Results: Professionals realize that Telemedicine is inserted into their usual practice in an informal way. They consider telemedicine as an alternative to the traditional delivery of health care, but are afraid of their role in health care is undermined. Professionals point out very specific applications of Telemedicine such as monitoring the health of patients remotely, drug doses adjustments and sharing clinical information. Conclusion: Results suggest that professionals are not familiar with telemedicine and will be necessary to develop a training plan before implementation.

Telemedicine, Telehealth, Qualitative Research.

Introduction

Healthcare system of Argentina is highly segmented, inequitable and heterogeneous. Three important challenges are, get better access to services, increase the quality of care, and lower the costs. Healthcare Information Technologies comprises a set of tools that offer an opportunity to overcome the challenges and Telemedicine is postulated as a viable, reliable and useful discipline. Several studies have attempted to collect data about healthcare professionals' expectations and opinions on telemedicine. Evidence found is controversial, although most of them report that available technologies are acceptable and easy to integrate, they believe its necessary to establish improvements to make them more reliable and adaptable to users' workflow.

Hospital Italiano de Buenos Aires is planning to develop a new healthcare model based on telemedicine using the Electronic Health Record and the Personal Health record. The aim of this study is to understand healthcare professionals' expectations, opinions and prior knowledge about telemedicine as part of the project's first stage.

Methods

A qualitative study based on in-depth interviews and focus groups was conducted in November and December of 2014. Content analysis was performed using Grounded Theory and NVIVO.

Results

Twenty five professionals (medical and non-medical) participated in 5 in-depth interviews and 2 focus groups. Participants' specialties were Family Medicine, Pediatrics, Psychiatry, Psychology, Nursing, Internal Medicine, Surgery, Dermatology, Nutrition and Lactation. Participants agreed that "Telemedicine" is a form of remote communication:

"I guess its medicine in the world of telecommunications where television and Internet are essential in everyone's life".

Professionals identified phone, email and Skype as tools used to communicate remotely with colleagues or patients:

"I had remote-live-supervisions using Skype, since the other therapist lived far away".

"Sometimes I give medical counseling to patients using Skype, I find it very useful".

Different opinions were emerging referring to the physician-patient relationship, the role of the institution, and the perception they have about this healthcare modality. They report that it's important to have a previous relationship with the patient before using telemedicine:

"It´s useful with patients that I already know because a previous relationship has been established".

Professionals are concerned about the use that patients make of these tools and are afraid of losing professionalism in the doctor-patient relationship:

"Patients use the email to medical consultations and for request to an appointment. Others use "Whatsapp" and this is not formal".

Professionals are also concerned about the role of the institution regarding the regulation of these new practices:

"Patients have no limits: call you late at night for small queries and not for actual emergencies. The institution has the role to create norms and procedures on how to handle these communication devices".

At the chance of using Telemedicine at their daily workflow they foresee communication with other professionals or education contexts. They said Telemedicine is not useful if the reason for consultation required physical examination:

"I think it's a useful tool for people who live far away, but if you have to touch the patient is not helpful".

Conclusions

Results suggest that professionals were not familiar with this kind of healthcare delivery. They found difficult to imagine how telemedicine would be implemented into their daily workflow. For future implementation, it will be necessary to design a training plan for health care professionals and change management strategies.

Future Telehealth and Telecare Reference Design based on IoT Technologies: From Remote Monitoring to Smart Collaborative Services with Decision Support

Martin Gerdes, Frank Reichert, Jan Pettersen Nytun, Rune Fensli[a]

[a] *Department of Information and Communication Technology, University of Agder, Norway*

Abstract

The demographic changes are producing aging societies across the world, resulting in greater demands on the health and care systems due to age-related disabilities and chronic diseases. Efficient telehealth and telecare services are needed to control the corresponding expenditures, by supporting increased collaboration between different professional and involving informal health care providers, and by empowering the patients to manage their health and well-being.

Emerging trial systems for remote patient monitoring present preliminary solutions not exempt of certain limitations. We propose a future eHealth reference system architecture and core components, aiming at secure, smarter and more collaborative telehealth and telecare services. The implicit cooperation between the so-far separated domains of consumer well-being services and public telehealth and telecare services will be beneficial for all parties.

Keywords:

eHealth; health informatics; telehealth; telecare; Internet of Things; ontologies; EHR; distributed decision support.

Introduction

An increased efficiency of the development, operation and utilization of telehealth solutions requires a smarter and adaptive device platform for data collection and communication in the point-of-care, distributed reasoning and decision support, and a secure storage and provisioning infrastructure. This has to support the cooperative access to health data and information (Core-EHR, P-EHR, other records) for professional and informal health and care providers, enforcing also privacy protection and access control.

Methods

For the EU FP7 project United4Health a trial system for remote monitoring of COPD patients at home has been developed and deployed in the secured Norwegian National Health Network (NHN). The solution provides routine measurements and questionnaires for the patient, and a secure and collaborative provisioning of the results to professional health care sources via an Information Integration Platform (IIP) and a dedicated NHN telehealth Web portal service.

Results

The result is a Secured Health Cloud infrastructure for commercial well-being, health and care services, complementing the NHN infrastructure on top of a common authentication and access control system as part of the overall Health Information System (HIS) infrastructure. The proposed point-of-care device platform will be personalizable for the patients' needs, utilizing smart sensors and ontologies for the individual data and as basis for adaptable, remotely manageable software modules for distributed decision support and user interaction.

Conclusions

The proposed reference architecture provides the basis for secure collaboration between commercial, professional and informal health and care sources, enabling personalized, smarter, and more efficient health and care services.

The EU-project United4Health: User-Centred Design and Evaluation of a Collaborative Information System for a Norwegian Telehealth Service

Berglind Smaradottir[a], Martin Gerdes[a], Santiago Martinez[a], Rune Fensli[a]

[a] *Centre for eHealth and Healthcare Technology, University of Agder, Norway*

Abstract

This study presents the user-centred design and evaluation process of a Collaborative Information System (CIS), developed for a new telehealth service for remote monitoring of chronic obstructive pulmonary disease patients after hospital discharge. The CIS was designed based on the information gathered in a workshop, where target end-users described the context of use, a telehealth workflow and their preferred ways of interaction with the solution. Evaluation of the iterative refinements were made through user tests, semi-structured interviews and a questionnaire. A field trial reported results on the ease of use and user satisfaction during the interaction with the fully developed system. The implemented CIS was successfully deployed within the secured Norwegian Health Network. The research was a result of cooperation between international partners within the EU FP7 project United4Health.

Keywords:

Health Information Systems; Information and Knowlegde Sharing; Usability; Telehealth; User-Centred Design.

Introduction

The research project United4Health (U4H) [1] aims to evaluate patient experiences with telehealth in Europe. In the Norwegian contribution to U4H, a solution was developed for remote monitoring of chronic obstructive pulmonary disease (COPD) patients. A Collaborative Information System (CIS) was built for information management and efficient communication in a new telehealth service, with a focus on sustainable operation and implementation within the secured Norwegian Health Network. This poster presents a summary of the results from the user-centred design (UCD) and evaluation process of the CIS from operational and qualitative usability perspectives.

Methods

The UCD process started with a workshop where representatives of the different end-user groups described the context of use and the preferred ways of interaction with the solution. The outcome was used to define user requirements to inform the CIS design. Evaluations of iterative refinements which included semi-structured interviews and a Satisfaction Usability Scale (SUS) questionnaire were made with end-users in the usability laboratory of the University of Agder, Norway. A final evaluation of the CIS was performed through a field trial before its deployment. Qualitative methods for data collection and analysis were employed during the UCD process, which had a total duration of 6 months.

Results

Based on the design input from the workshop, the first version of the CIS was implemented. Representative end-users iteratively tested the implementation in the usability laboratory. In the first evaluation, 9 usability issues were identified related to the GUI, among which 1 major issue was related to the colour scheme selected that could interfere with the coloured evaluation of patient *triage*. Consequently, a grey scale colour scheme was advised. Users made 9 suggestions about the functionality of the system, such as having the option to manually override the automatically calculated patient *triage*. The second user evaluation showed that the new GUI colours improved information overview and the manual override functionality was evaluated as successful. Answers from the SUS questionnaire presented high score of satisfaction. Results from the field trial showed that users' overall rating concerning the interactions with the CIS was satisfactory. In addition, the CIS was reported by users as "*easy to navigate*" and the display of critical information at the top of the GUI was valued as "*positive*". One of the participants stated during interview: "*The CIS seems to work well and gives a good overview, most of it is self-explained*".

Conclusion

The UCD process effectively included users' needs in the design process of the Collaborative Information System for a Norwegian telehealth service for remote monitoring of COPD patients after hospital discharge. The workshop with representative end-users allowed gathering of key information regarding data visualisation and system requirements. The evaluation comprised a series of iterative user tests that led to the refinement of the GUI and functionality of the system. In addition, a field trial provided both real-time evaluation and continuous observation of long-term use of a fully developed telehealth system in working environment, contributing to the ecological validity of the study. The CIS has been deployed by the EU FP7 project U4H partners currently being used by three telehealth service centres in Norway.

Enhancing tele-collaboration Networks by Patient Participation

Martin Staemmler[a], Heiko Münch[b], Uwe Engelmann[b], Johannes Sturm[c]

[a] *University of Applied Sciences, Stralsund, Germany*
[b] *Chili GmbH, Dossenheim, Germany*
[c] *Akademie der Unfallchirurgie GmbH, München, Germany*

Abstract

This paper decribes an approach for extending tele-collaboration to the patient and allowing the patient's participation by accessing and providing data and thereby keeping the responsibilty for maintaining a personal health record with the patient. The approach has been implemented and is in use with the nationwide tele-collaboration network TKmed.

Keywords:
patient participation; privacy; personal health record

Introduction

Conventional tele-applications like teleradiology or telepathology involve professional users in a doctor to doctor setting. Nearly all of the tele-applications lack the involvement of the patient. On the one hand these include access to the data for viewing and downloading and on the other hand the ability to upload and provide data to institutions or organisations, respectively doctors, as preparation for a patient visit or consultation for example. This poster presents an approach for extending existing tele-application systems through a patient-centric functionality without compromising current use and in particular privacy and data security. To illustrate the approach the established tele-collaboration system TKmed [1] is used.

Methods

TKmed is a nationwide tele-collaboration service currently being used in more than 120 hospitals and practices mainly in Germany and in some of the adjacent nations in cross-border scenarios. It supports tele-applications like teleradiology and telecardiology and includes a consulation workflow support.

Two patient-centric use cases have been identified by consulting patients: (i) Data object uploading for preparing a patient visit to a practice or hospital and (ii) viewing and downloading of data objects in the context of a patient visit. From an IT point of view there is an unidentified and unregistered patient requirement of access to a highly secured tele-collaboration infrastructure. Allowing a direct one step upload to registered users is prone to spam. Instead a two step upload is needed including a light weight registration by entering the patients email address and selecting the institution in the first step. Having activated the link received by email the user selects data objects and starts the upload. Data objects can be ordinary files of any type as well as individual DICOM objects from a CD or organized by a DICOMDIR.

The second use case is limited to the patient as a recipient thereby relying on a simplified consent based on the doctor-patient interaction during treatment with an intrinsic identification. To assure that only the patient is able to access data, a two-factor authentication has been established based on knowledge (login and password for the patient's email account for receiving a link) and a token generated by a TKmed application and printed at the institution (ownership) and handed over to the patient. The token is the result of a hash of demographic data and a secret provided by Tkmed at running time.

Results

Both use cases have been implemented in TKmed using a Java application being executed in the browser. The services were released to several hospitals at the end of 2014. The evaluation will be based on online questionnaires sent to the users assessing the usability of the applications and feedback regarding this support for patient participation. The first evaluation results will be available in time for the Medinfo 2015 conference.

Discussion

Exchange of information between patients and professionals depends on the eHealth literacy of the healthcare system and the institutions involved. Well-advanced, electronic record based environments support mutual access but require a sophisticated infrastructure for identity and access management based on a public key infrastructure and token. Enhancing an established tele-collaboration system is a lightweight and targeted way to achieve direct acceptance by clinical users. Patient participation has proven its usefulness for supporting patient compliance and also in taking an active role to maintain and improve the personal health status [2]. Providing such services by healthcare organisations offers a new way and has good chances of improving and fostering the relationship with the patient.

The Effect of Mobile App Follow-up Care on the Number of In-person Visits Following Ambulatory Surgery: A Randomized Control Trial

Kathleen Armstrong[a,b], Peter Coyte[b], John Semple[b,c]

[a] *Division of Plastic & Reconstructive Surgery, University of Toronto, Toronto, ON, CAN*
[b] *Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, CAN*
[c] *Department of Ambulatory Surgery, Women's College Hospital, Toronto, ON, CAN*

Abstract

Women's College Hospital (WCH) in Toronto offers specialized ambulatory surgical procedures. A feasibility study using a mobile appliciation (app) to supplement in-person follow-up care after surgery suggests that the mobile app adequately detects postoperative complications, eliminates the need for in-person follow-up care and is cost-effective. This is concordant with other postoperative telemedicine studies.

The purpose of this study is to determine if we can avert in-person follow-up care through the use of mobile app compared to conventional, in-person follow-up care in the first month following surgery amongst breast reconstruction patients at WCH. This will be a pragmatic, single-centre, open, controlled, 2-arm parallel-group superiority randomized trial.

Mobile app follow-up care is a novel approach to managing patients postoperatively with the potential to avert in-person follow-up and generate cost-savings for the healthcare system and patient.

Keywords:

mobile app; ambulatory surgical procedures; postoperative care; telemedicine; health services research

Introduction

Women's College Hospital (WCH) offers specialized ambulatory surgical procedures. Patients often travel great distances to undergo surgery. Most patients receiving ambulatory surgery have a low rate of postoperative events necessitating clinic visits. Regular follow-up is still considered important in the early post-operative phase. Telemedicine data suggests that mobile monitoring and follow-up care is valued by patients and can reduce costs to society [1,2].

In a feasibility study at WCH, a mobile app (QoC Health Inc., Toronto) was used to supplemement in-person postoperative follow-up care in breast reconstruction patients. Preliminary studies suggest that mobile app follow-up care is feasible, can avert in-person follow-up care and is cost-effective from a societal and health care system perspective [3].

Materials and Methods

This is a pragmatic, single-centre, open, controlled, 2-arm parallel-group superiority randomized trial comparing mobile app and in-person follow-up care over the first month following surgery. Permutated-block randomization was conducted by blocks of 4-6 using the program ralloc in Stata 13.1 (2014, StataCorp, TX).

Patient Population: All postoperative ambulatory surgery patients undergoing breast reconstruction at WCH.

Intervention: Post-operative mobile app follow-up care using the quality of recovery-9 (QoR9) and a pain visual analog scale (VAS), surgery-specific questions, surgical site photos, and frequency of submissions as defined by the surgical team.

Outcomes: The primary outcome is the total number physician visits related to the surgery over the first month postoperative. Secondary outcomes include: 1) the total number of phone calls and emails to a health care professional related to surgery; 2) complication rate; 3) societal and health care system costs; and 4) patient satisfaction over the first month postoperative.

Sample Size: If we assume that at least one in-person visit is averted in the mobile app arm, an E-test for count data generates a sample size of 70 (35 patients per group) at a power of 95 percent (p=0.05) with a 10% drop out rate.

Analysis: Count variables will be analyzed using poisson regression. Categorical variables will be tested using a chi-square test. Cost-effectiveness will be measured using net benefit regression.

Results

Results available in June 2015.

Impact of a mobile health aplication in the nursing care plan compliance of a home care service in Belo Horizonte, Minas Gerais, Brazil

Felipe A. de Britto[a], Tatiana B. Martins[b], Gustavo A. P. Landsberg [c]

[a] *Health Information Technology Management of Unimed BH, Belo Horizonte, Brazil*
[b] *Home Care Management of Unimed BH, Belo Horizonte, Brazil*
[c] *Health Information Technology Management in Unimed BH, Belo Horizonte, Brazil*

Abstract

Objective: To assess impact of a mobile health solution in the nursing care plan compliance of a home care service. Methods: A retrospective cohort study was performed with 3,036 patients. Compliance rates before and after the implementation were compared. Results: After the implementation of a mobile health aplication, compliance with the nursing care plan increased from 53% to 94%. The system reduced IT spending, increased the nursing team efficiency and prevented planned hiring. Conclusion: The use of a mobile health solution with geolocating feature by a nursing home care team increased compliance to the care plan.

Keywords:

Home Care Services; Patient Care Planning.

Introduction

Managing a home care team and evaluating compliance to the nursing care plan has always been a difficult task, due to the scope, geographical distribution and number of professionals involved. Studies show that the frequency of home visits by health professionals significantly impacts in hospital-free time of the patient [3]. The objective of this study was to assess the impact of a mobile health solution on the nursing care plan compliance by a home care service.

Methods

A retrospective cohort study was performed with the data from 3,036 patients treated between December 2013 and November 2014 by the Unimed-BH Home Care Program. All patients treated by the nurses with a Case Management care plan during this time period were considered eligible. The information on patients whose nurse visit interval was shorter than 35 days was extracted from the database of the care/administrative system, and compliance to the nursing care plan before and after the mHealth tool implementation was compared.

Results

Before the implementation of the mobile solution, care plan compliance rates were assessed quadrimestrally and were as low as 53% from January to April 2013 and 54% from May to August 2013. After the first phase of implementation, in November 2013, nursing care program compliance rates were vastly improved, increasing to 78%. After the implementation of the second phase in August 2014, nursing care plan compliance reached 94% between September and November 2014. During this period there was a small decrease of average portfolio patients compared with the previous three months (Table 1). This decrease was the result of hiring new workers in August and September. The company had forecasted nurse hirings for October and November in order to match the increasing number of patients, but as the rate of nursing care plan compliance reached satisfactory levels, the hiring of additional nurses was not deemed necessary.

Table 1– Compliance with care plan after the implementation

Period	Compliance with care plan	Average patients in the portfolio	Average daily visits
Dec/13- Feb/14	78%	65	3.28
Mar/14-May/14	79%	65	3.32
Jun/14-Aug/14	81%	64	3.49
Sep/14- Nov/14	94%	63	3.59

Discussion

The implementation of a mobile solution made clinical data in-puts easier and clinical nursing processes simpler to control. It increased compliance with the plan of care indicators, reduced IT spending, increased the team average production capacity and prevented planned hires.

Conclusion

The increasing usage of home care programs as an alternative to hospital-centered model creates complex problems that require new solutions. The use of mobile health tools may help to increase the compliance to the care plan by making patient's portfolio easier to manage and enable better planning for future visits.

Augmented Reality: Real-Time Information Concerning Medication Consumed by a Patient

Gloria Diodati[a], Adrián Gómez[a], Marcela Martínez[a], Daniel Luna[a], Fernán González Bernaldo de Quiros[a]

[a]*Departamento de Informática en Salud, Hospital Italiano de Buenos Aires, Argentina*

Abstract

This paper describes a mobile prototype capable of recognizing characters from a photograph of a medication package. The prototype was built to work on the iOS platform and was developed using Objective-C and C programming languages. The prototype, capable of recognizing text out of an image, included image processing algorithms, text processing algorithms, and techniques to search and handle information from a database. This prototype is presented as an option for capturing reliable and validated information by using new technologies available to the general population.

Keywords:

Personal Health Record, Mobile Health, Optical Character Recognition, Image Processing.

Introduction

Self-medication is common, so a process for registering medications used by a patient is essential for finding discrepancies and improving the effectiveness and safety of treatments. Personal health records (PHR) facilitate doctor-patient communication and allow the patient to participate actively in self-care.

The objective of this paper is to describe the tools and algorithms used to build a mobile prototype that can recognize text from a photograph of a medication package. Integration between the PHR and this prototype is not described in this paper since the prototype is still in the conceptual definition stage. Likewise, the prototype has not been tested with real patients.

Materials and Methods

A prototype was built to work on the iOS platform and developed using Objective-C and C programming languages.

Results

During the first phase of this work the image was resized to 640 by 640 pixels. Next, the image was converted to grayscale and an engine named Tesseract was invoked to recognize characters as text. With the data obtained from this procedure, all the characters that did not belong to the alphanumeric set were removed and all words containing fewer than three characters were ignored. Then, the Levenshtein distance between the recognized words and the ones in a product database was calculated in order to select those with the smallest possible edit distance. Following this procedure, the product and its main components were identified.

Table 1 – Accuracy after first phase

Complete	Partial	Error
41.66%	6.25%	6.25%

Table 2 – Average time to process images recognized during first phase

	First processing	Call to Tesseract engine	Text processing	Text validation	Database search
Time (s)	0.0435	0.4951	0.0055	0.8637	0.1573

In the second phase the images were processed with a thresholding algorithm as a segmentation method. The threshold value used for this task was the mean value of the pixels of each image. Once preprocessing of the image stage finished, the Tesseract engine was invoked again and the text processing method was repeated. With this information we looked up the product in a database and got the pharmaceutical information.

Table 3 – Accuracy after second phase

Complete	Partial	Error
33,33%	2.08%	8.33%

Table 4 - Average time to process images recognized during second phase

	Second processing	Call to Tesseract engine	Text processing	Text validation	Database search
Time (s)	0,0499	0,3201	0,0648	0,5842	0,2505

Conclusion

Patients' communication with the doctor about medicine consumption is necessary for the doctor to make accurate diagnoses. This prototype can capture medication information using new technologies available to the population.

Description of a Mobile-based Electronic Informed Consent System Development

Min-A Hwang, In Ja Kwak

Information Office, Seoul National University Hospital, Korea

Abstract

Seoul National University Hospital constructed and implemented a computer-based informed consent system in December 2011. As of 2013, 30% of the informed consents were still filled out manually on paper. Patients and medical staff continuously suggested the implementation of a system for electronic informed consent using portable devices. Therefore, a mobile-based system for electronic informed consent was developed in 2013 to prevent the issues that arise with computer-based systems and paper informed consent. The rate of filling out electronic informed consent increased from 69% to 95% following the implementation of the mobile-based electronic informed consent. This construction of a mobile-based electronic informed consent system would be a good reference point for the development of a mobile-based Electronic Medical Record and for various mobile system environments in medical institutions.

Keywords:
Computer Systems; Informed Consent; Mobile Apps

Introduction

In December 2011, Seoul National University Hospital developed a system where patients could fill out electronic informed consent to prevent the issues that arise with paper informed consent. However, paper informed consents were unavoidable when the patients had motor coordination problems, or they had to fill out the informed consent at a location where a computer was not set up.

Therefore, the percentage of those who filled out the electronic informed consent was only about 69%, on average. Further, the paper informed consents were available by default, so some of the required responses were not filled out; therefore, the main issue with using paper informed consent was still present. To avoid this, the researchers developed a mobile-based system for electronic informed consent.

Methods

The system for mobile-based electronic informed consent was constructed from June 2014 to August 2014. Departments and medical staff that usually have their patients fill out informed consent worked together on this project. The mobile devices used in the electronic informed consent development were selected based on the following criteria:

- Easy-to-read screen, Portable size and weight
- Drawing feature and Durable
- Affordable

The following features of the mobile-based electronic informed consent were selected and applied:

- Included drawing features
- Supported certified electronic signature modules
- Prevented forgery by saving captured images

Patients and medical staff in all departments, emergency rooms, and examination rooms began filling out electronic informed consent using mobile devices in September 2014.

Results

The rate of filling out electronic informed consent increased from 69% to 95% following the implementation of the mobile-based electronic informed consent. Thirty-five percent of the electronic informed consent were mobile-based. Scanning paper informed consent decreased to 50%, and the mobile electronic system prevented the respondents from missing required responses.

Interns and medical doctors were mainly the ones who filled out the informed consent, and they were interviewed regarding their feedback on the mobile-based electronic informed consent. They gave mostly positive feedback on the portability of the device, but they offered negative feedback concerning the following features:

1. Using fingers to draw and write letters is not user-friendly.
2. Takes a longer time to fill out responses on the mobile device than on paper.
3. Wi-fi can be unstable at times.

Conclusion

Implementing mobile-based electronic informed consent decreased the scanning work and lowered the required response miss rate to 0%. However, we cannot assume that these responses were more accurate, or that the questions were written more thoroughly. Quality evaluation of the electronic informed consent will be continuously out forward to secure the patients' right to know and the medical staff's responsibility to explain everything thoroughly to the patients.

Exploring the Challenges and Opportunities of eHealth Tools for Patients with Sickle Cell Disease

David-Zacharie Issom[a], Alexandra Zosso[b], Frederic Ehrler[c], Rolf Wipfli[c], Christian Lovis[c], Sabine Koch[a]

[a]*Department of Learning, Informatics, Management and Ethics, Health Informatics Centre, Karolinska Institutet, Stockholm, Sweden*

[c]*Division of Medical Information Sciences, University Hospitals of Geneva, Geneva, Switzerland*

Abstract

Sickle cell disease (SCD) is the most prevalent inherited blood disorder in the world. The symptoms decrease the quality of life of patients and can cause premature death. Self-help solutions for chronic patients are rising and increase the quality of life of patients. We are interested to identify the usefulness of eHealth tools for patients with SCD. We did a literature review to identify the main problems faced by patients and the existing eHealth solutions. The results show a low number of studies in the field but a multi-disciplinary interest. Positive health benefits for patients are reported as well as the need for more research. Patients and caregivers lack of education about the disease, healthy behaviors are unknown and clinical best practices underused. E-health tools can offer an appropriate support for the self-management of SCD by improving the quality of life of patients, by enhancing patient health literacy and by allowing clinicians to make better decisions.

Keywords:

Sickle Cell Disease, eHealth, mHealth, telemedicine, self-care, self-management, self-monitoring, wearable devices.

Introduction

Sickle Cell Disease (SCD) is a complex hereditary form of anemia affecting millions of people throughout the world. Patients mostly suffer from painful and debilitating vaso-occlusive crisis (VOC) lasting around 7 days. Usually, they are managed at home, and patients seek hospitals only when the pain cannot be controlled anymore or when life threatening complications occur. Patients can reduce the occurence of crisis with a good self-care. For instance by following a healthy diet, keeping a moderate body temperature, avoiding tiredness, low oxygen level and by taking appropriate medicine. Consequently, eHealth tools have an important role to play, as demonstrated with the self-management of patients with diabetes [1].

Methods

We performed a literature review to identify the main problems faced by patients and the existing e-Health solutions. We used the term “sickle cell disease” with the terms “system”, “mobile”, “cellular”, “self-management”, ”mHealth”, *OR* ”telemedicine” and searched in the usual data sources.

Results

We identified 15 relevant studies and listed them in Table 1.

Table 1 – Relevant studies of eHealth solutions for SCD

Discussion and Conclusion

The low number of studies indicates little interest in the field but some papers proved the importance of using eHealth tools for SCD and showed various solutions. Patients often suffer from a lack of coordinated care and from a bad understanding of their needs. This is due to the relative uncommonness of the disease. Limited financial resources, poor patient health-literacy and existing beliefs can also prevent patients from making the most valuable health choices. Therefore, using eHealth to provide trustworthy information is recommended. The reviewed papers show that eHealth tools can be useful for self-monitoring purposes. Few work has been actually done, but the potential of improving health outcomes is great. Because the disease is often not diagnosed, mobile technologies can facilitated the screening and the diagnosis phases. A change in patients’ behavior can be influenced with mobile applications helping them to adopt and follow healthy practices, such as with daily advices or notifications. Further studies need to assess which technologies are able to tackle the main unmet patient needs.

Development and Usability Evaluation of the Mobile Delirium Assessment App Based on Confusion Assessment Method for Intensive Care Unit (CAM-ICU)

Meihua Ji[a], Ying Wu[a], Polun Chang[b], Xin Yang[c], Fangyu Yang[a], Shuang Xu[a]

[a] *School of Nursing, Capital Medical University, Beijing, China*
[b] *Institute of Biomedical Informatics, National Yang-Ming University, Taipei, Taiwan*
[c] *Affiliated Xuanwu Hospital, Capital Medical University, Beijing, China*

Abstract

Delirium is a common complication among patients in ICU settings. The accuracy of using the assessment tool CAM-ICU to detect delirium is relatively low during routine practice among bedside nurses. The aim of this study is to develop a mobile application (app) to detect delirium in early stage and to test its usability among ICU nurses. The app was developed with Java and installed on a mobile device. A questionnaire was created based on the Technology Acceptance Model (TAM) measuring their response to the four domains of TAM: perceived usefulness (PU), perceived ease of use (PEOU), attitudes towards usage (ATU) and behavioral intention to use (BIU). One hundred and two ICU nurses completed the survey. The result indicated that the app we developed has easy to use interfaces and is easier to use compared to the regular CAM-ICU.

Keywords:
Mobile Application; CAM-ICU; Delirium.

Introduction

Delirium is one of the most common complications of ICU patients and can adversely affect patients' short and long-term outcomes. It should be monitored regularly using CAM-ICU as reccomended by American College of Critical Care Medicine. Although the acuracy of CAM-ICU in detecting delirium is reported repeatedly high (> 90%) in research papers, its sensitivity and specificity are only around 50% when it was used in routine nursing practice due to lack of adequate training, inaccurate and incomplete interpretation of assessment data or using variable patient baselines when making the diagnosis [1]. The purpose of this study is to develop a standardized and easy to use mobile CAM-ICU delirium detecting app for bedside nurses and test its usability.

Materials and Methods

This study includes two phases: development of the mobile app and evaluation of its usability. The app was designed with JAVA and installed on a mobile device. A modified usability evaluation questionnaire of TAM, which includes four domains and 46 items and rated with 5-Likert scale, was used to test the usability of the developed app. There are 4 items comparing the level of easiness between the mobile app and regular CAM-ICU. Convenience sampling was used, and nurses from ICU settings of three hospitals completed the questionnaire after using both mobile and regular CAM-ICU tools.

Results

The screenshots of the app are shown in Figure 1. The app was programmed to automatically retrieve baseline data for comparision and print out the result on whether or not the patient has delirium.

A total of 102 ICU nurses participated to test the usability of the mobile CAM-ICU app. The means of the four domains regarding to the app are: PU: 4.09-4.22, PEOU: 4.07-4.33, ATU: 3.90-4.16, BIU: 3.97-4.24. The Cronbach's α of each demain is 0.936, 0.949, 0.902, 0.915. The means of the four items that compare the mobile app and regular CAM-ICU are 4.14, 4.17, 4.23, 4.23, indicated that nurses have perceived the app as easier to use compared to the regular CMA-ICU.

Figure 1. Application Screenshots

Conclusion

The mobile CAM-ICU app we developed has easy to use interfaces. The evaluation indicates that this is a useful tool in delirium assessment and easier to use compared with regular CAM-ICU, especially in guiding nurses through assesment accurately and observing patient's condition comprehensively.

Viability of a Bioelectrical Signal Acquisition System Energized by Cellphone with NFC

Marcel Seiji Kay, Fábio Iaione

Faculty of Computing, Federal University of Mato Grosso do Sul, Campo Grande

Abstract

Currently, smartphones are used in various systems in the medical field due to the presence of various features, notably Near Field Communication (NFC). NFC utilizes communication technology and an energy supply based on electromagnetic induction. One of the most common medical tests is the electrocardiogram (ECG), through which various heart diseases can be diagnosed. The objective of this study is to evaluate the feasibility of providing power to a bioelectrical signal acquisition module using a mobile phone with NFC. After testing it was indicated that it is possible to construct a passive module to acquire ECG signals using NFC mobile phone.

Keywords:

Electrocardiogram; Near Field Communication; M-health.

Introduction

The use of passive devices in the medical field is a relatively common practice, especially when they need to be implanted [1], where having no battery is a very interesting feature. In passive systems, data communication and transfer of energy occur through inductive coupling between planar coils [2]. The energy transfer by this method is approximately 80% at a distance of 15 mm [3]. The depth of penetration of electromagnetic waves on living tissue decreases significantly with increasing frequency, so the frequency of the Radio Frequency Identification (RFID) systems used in living tissue is between 125 KHz and 40 MHz [2,4]. Smartphones have great processing power, storage, visualization and communication, including Near Field Communication (NFC), and are already used in the medical field. One of the most commonly performed medical tests is the electrocardiogram (ECG), which can diagnose various heart diseases, thus enabling a pretreatment to prevent possible sequelae. Accordingly, the objective of this study is to assess the feasibility of providing power to a bioelectrical signals acquisition module using a mobile phone with NFC.

Methodology and Results

In this study a reimplementation of the bioelectric signals acquisition module described in [5] was used. This module performs conditioning, digitization and transmission of the EEG signal captured. It can also capture the ECG signal reducing the gain of the amplifiers. The module is powered by a battery whose voltage is regulated to 5V, with a current of 17 mA (P = 85mW). The transmission of the digitized signal is performed by serial infrared at 9600 bps. Table 1 shows the electric current of several components.

A test was conducted using a mobile phone, Samsung model GT-I9250, and a rectangular coil of four turns (26 AWG), measuring 4 x 8 cm. In this test, loading of 1500 ohms was measured as a sinusoidal signal (13.56 MHz) of 10 Vpp (peak-to-peak voltage), indicating transferred power of 8.33 mW.

Table 1 – Components of the module and their currents

Component	Current
Instrumentation Amplifier (AD627) and Operational Amplifier (TS912)	785 uA
Microcontroller (AT89C2051 @ 11.092 MHz) and ADC (MAX187)	12 uA
Voltage regulators (2 x LP2950-50)	400 uA
Infrared serial communication (LED)	4 uA

Conclusion

Exchanging the microcontroller by C8051F320 (internal ADC) which consumes 0.6 mA (at 1 MHz), and removing the infrared communication, the power module can be reduced to approximately 8.9 mW (5V x 1.785 mA), which is compatible with the measured transferred power. Furthermore, it is also possible to optimize the number of coil turns, increasing the power transferred. Therefore, it is possible to construct a passive module for acquisition of bioelectrical signals without energy source, using an NFC mobile phone to display the signal and power supply.

Smart Glasses – A New Tool in Medicine

Gunnar O Klein[a], Karandeep Singh[b], Johan von Heideken[c,d]

[a] *Dept. of Informatics, Örebro University, Örebro, Sweden*
[b] *Dept. of Medicine, Harvard Medical School, Boston USA*
[c] *Dept. of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*
[d] *Department of Physical Therapy, Movement and Rehabilitation Sciences, Northeastern University, Boston USA*

Abstract

Smart glasses, defined as a computerized communicator with a transparent screen and a video camera, wearable as a pair of glasses, have started to be tested for a variety of health related applications. This poster reviews some of the early experiences and gives a series of proposals for possible uses in medicine with a particular emphasis on medical education.

Keywords:

Clinical informatics; Educational models; Google Glass.

Introduction

Smart glasses have the following set of features:

- A hands free communicator, that can communicate via Bluetooth with, for example, a smart phone, or directly with the Internet when Wi-Fi is available.
- A video camera and voice recorder/transmitter.
- A display for viewing text and images.
- A voice input interface.

The most published product today is Google Glass which has been available for pilot beta tests since February 2013. Like tablets and smart phones, smart glasses are a platform for various applications [1]. They were not specifically targeted at health care but there are already numerous pilots supporting various medical applications. On January 15, 2015 Google announced [2] that the production of the Glass prototype was stopped but Google remains committed to the development of the product.

Methods

This poster is based on a literature review of 17 full papers.

Results

Since their release, smart glasses have been tested in health care for a variety of applications using limited numbers of patients and reported in various news media and conferences. Our literature review found seventeen scientific papers which provide a clinical evaluation of these new devices. In addition to monoapplication papers, Muensterer *et al* had a pediatric surgeon wear a glass device throughout the day for four weeks and recorded possible situations where the technology might assist. These papers provide mostly promising results but also caution where the technology was deemed not suited for the tested application, for example for ECG interpretation and autopsy documentation.

Table 1 – Different application areas described

Application area	Findings
Remote instruction of users wearing Glass	Beneficial use in cardiologist education, Orthopedic surgery training, Cancer surgery, Central venous access, Ultrasound interpretation, and in Diabetic limb assessment
Documenting procedures	Autopsy documentation, Airway intubation
Patient empowerment	Allergy patients getting access to information, Macula patients getting augmented vision
Reading signal data	ECG assessment, Immunochromatography, Vital signs during radiological intervention
Providing instructional films and simulation	Disaster medicine, Anatomy and palpation

Discussion

There are many potentially important applications of this new technology in medical education both for remote supervision and for the production of educational films. The usefulness in clinical practice, for example for seeking a second opinion or providing assistance to the workflow or reading of adapted EHRs remains to be studied.

Abstract

The assessment of shelters during disaster is critical to ensure the health of evacuees and prevent pandemic. In the Ishinomaki area, one of the areas most damaged by the Great East Japan Earthquake, the highly organized assessment helped to successfully manage a total of 328 shelters with a total of 46,480 evacuees. The input and analysis of vast amounts of data was tedious work for staff members. However, a web-based assessment system that utilized mobile devices was thought to decrease workload and standardize the evaluation form. The necessary access of information should be controlled in order to maintain individuals' privacy. We successfully developed an access control system using IDs. By utilizing a unique numerical ID, users can access the input form or assessment table. This avoids unnecessary queries to the server, resulting in a quick response and easy availability, even with poor internet connection.

Keywords:

Disaster; Shelter; Mobile; Assessment.

Introduction

The magnitude-9.0 Great East Japan Earthquake struck the northeastern coast of Japan on the 11th March 2011, resulting in 15,889 dead, 2,597 missing, and 6,152 injured persons, as of August 2013. During the disaster, many people (around 400,000) were evacuated to temporary shelters, such as public halls, gymnastic halls, and schools in Northeast Japan. One of the most damaged areas was Ishinomaki, which had a total of 328 shelters with a total number of 46,480 evacuees. Cooperating with various pertinent institutions—such as the Miyagi Prefecture government, the Ishinomaki municipal government, the local medical association, the Tohoku University Hospital, and the Japan self-defense forces—the Ishinomaki Zone Joint Relief Team consisted of physicians, nurses, public health nurses, pharmacists, and volunteers that were based in the Ishinomaki Medical Zone. This team managed a total number of 53,696 persons in evacuation shelters for almost six months [1]. During the management of disaster relief, the team continued a survey of medical and sanitary conditions, as well as environmental conditions, including power, gas, and water supplies. Their efforts resulted in successful and well-organized management, avoiding the development of pandemic. However, the process of evaluation, calculation, and analysis was associated with tedious work and high workloads for staff members. To decrease this burden, an assessment system that utilizes mobile devices was developed. This study details one of the requirements for the system and the means of meeting this requirement.

Methods

The software is a browser-based app that is available on the iPad. The database on the server is based on MongoDB. Since Internet availability is often poor under disaster conditions, the input data are able to be stored off-line and are sent to the server after re-connection to the Internet.

Results

The software has two main functions: data input and data management. A medical crew is required to input data on about 19 assessment factors, describing the current condition of shelters in the area, into the mobile assessment system. The headquarters of the area analyzes the collected data from the dispatched relief teams using assessment tables, contained within the mobile assessment system. In relation to both privacy and efficiency, controlled access to the system is required. The relief teams are limited to inputting data about the shelters that they are in charge of. The headquarters of the areas are then able to browse information on the shelters that they are charged with managing. Furthermore, senior command teams are able to access the information from a wide range of areas. These access control practices utilize ID numbers. For example, if 99 relief teams have IDs 101 to 199, then a relief team with ID 101 can access the information about shelters linked to ID 101, but cannot access information linked with other IDs. Furthermore, the headquarters with ID 100 that is in charge of crews with IDs 101 to 199 can access all the available information about the shelters linked to those IDs.

Conclusion

Our mobile assessment system is available for both headquarter and dispatched relief teams and utilizes access control with ID numbers. This system is useful for avoiding unnecessary queries to the server when internet connections are poor.

Acknowledgments

We are greatly thankful for the technical support of Jun Yamadera and Koichiro Amito (Eyes, JAPAN Co. Ltd.).

Using mobile devices to improve the safety of medication administration processes

Navas H[a], Graffi Moltrasio L[a], Ares F[b], Strumia G[c], Dourado E[a], Alvarez M[a]

[a] *Sanatorio Finochietto, Buenos Aires, Argentina*
[b] *Develaris, Buenos Aires, Argentina*
[c] *TIPS Salud, Córdoba, Argentina*

Abstract

Within preventable medical errors, those related to medications are frequent in every stage of the prescribing cycle. Nursing is responsible for maintaining each patients safety and care quality. Moreover, nurses are the last people who can detect an error in medication before its administration. Medication administration is one of the riskiest tasks in nursing. The use of information and communication technologies is related to a decrease in these errors. Including mobile devices related to 2D code reading of patients and medication will decrease the possibility of error when preparing and administering medication by nurses. A cross-platform software (iOS and Android) was developed to ensure the five Rights of the medication administration process (patient, medication, dose, route and schedule). Deployment in November showed 39% use.

Keywords:

Electronic Health Record; Mobile Applications; Medication Errors; Patient Safety.

Introduction

The prescribing cycle, which consists of five steps since the treatment is indicated until it becomes effective, contains errors at each step. The most common errors in medication preparation and administration are: dosage, frequency, route of administration, patient, starting time or suspension, medication, no medication administration, wrong infusion preparation, mishandling of infusion pumps, or inadequate record.

The nurse is the last person who can check if the medication was correctly ordered and dispensed before administration. Medication administration is probably the highest risk task a nurse can perform. Applying the Rights to medication administration can enhance patient safety and prevent harm. The use of barcodes during medication administration reduces the possibility of error. Our objective is to describe the mobile system developed and its inclusion in a safe medication process.

Methods

Sanatorio Finochietto is a private healthcare institution belonging to the *ASE (Acción Social Empresaria)* group, founded in November 2013, with over 150 adult inpatient beds and over 20 neonatal intensive care incubators, it has 6 intelligent general operating, 2 outpatient operating, 2 delivery and 2 antepartum rooms. It is the first bio-eco-smart medical center with a structure designed for a rational and responsible use of natural resources. It possesses a commercial Health Information System (HIS).

Nurses prepare the schedule for each indication in the "nursing Kardex". Each nurse reads the medical indication of each patient, opens the medication drawer of said patient, separates the indicated medications and places them on a tray. They then go to the patient's room with the prepared tray and administer the medication. Once all the medication has been administered to the patient, nurses return to the office to record the administration of the medication.

Results

A native application for mobile devices (iOS and Android) has been developed in .NET, deployed within the aforementioned system supporting the five Rights:

- Right time: The system issues a visible and audible alert (push), and enables the preparation of the medication from one hour before the scheduled timetable by nursing, until one hour later.
- Right dose and Right medication: The system displays the scheduled medication list pertaining to a certain timetable for the selected patient. As the user selects each medication from the list, the system enables the device camera to verify the code on the medication packaging.
- Right patient: Upon completion of a patient's medication preparation, the system enables the device camera to allow the nurse to read the code on the patient's wristband before administration.
- Right route: The system displays the prepared medication list grouped by route. Users checking such list administer the medication and mark the medication which has been correctly administered directly from the device display.

One sample of administration activity was taken on a weekday and on a weekend day in November 2014. Resulting in weekday numbers: 743 without device, 483 (39%) with device, weekend numbers: 982 without device and 188 (16%) with device.

Conclusion

The degree of user acceptance of the new technologies is directly related to the user experience and time-saving of tasks completed with the technology. User training and support are crucial to enhance acceptance, as well as support given to those users who regularly use the device. We must include a nurse who has the ability to lead development and chamption implementation on the team. The institution is still in the implementation stage this technology, and until this stage is completed, is it impossible to measure whether the use of this technology actually improves patient safety.

Study of Development for RFID System to Hospital Environment

Seung Kwon Hong[a], Myung-Whun Sung[b]

[a]*Division for BioMedical Informatics, Department of Family Medicine, School of Medicine, The Catholic University of Korea, Incheon St. Mary's Hospital*
[b]*Department of Otorhinolaryngology, Head and Neck Surgery, Seoul National University Hospital*

Abstract

RFID/USN develops information systems for anytime, anywhere to anybody access Electronic Medical Records (EMR). The goal of the present study is to develop a RFID/USN-based information system for the hospital environment. First, unable to recognize, second, able to recognize as a pursuit of place and suppose the time of medical examination. A retrospective analysis of 235 RFID monitoring results, from four ENT ambulatory clinics of Seoul National University Hospital were extracted by a reader program and monitoring of RFID tag (2006.11.16~2006.12.16). RFID detection for sensing reader of this study has been put into representing "place" and "spending time" of patients for medical history taking and examination. Through the RFID of detection for specific place and spending time of medical examination, RFID/USN develops information system progressing in the EMR of hospital system.

Keywords:

RFID, Electronic Medical Record, Hospital Information System.

Methods

This study researched 162 new registered patients at otolaryngology department at Seoul National University Hospital. The system comprised of RFID technology, RFID tags, reader, tag and a Reader to receive information exchanged between the servers or network bearer to middleware formation. The RFID antenna used for this study had a frequency of 902 ~ 928MHz and 5.73 dBi, 4 watts EIRP with a high-frequency power. The treatment room, hearing laboratory room, and hospitalization Reservations room where the RFID Reader was installed was from the ground to the reader center and average was 114 cm, with the entrance door widths being a maximum of 130cm and a minimum of 87cm. A reader installed in the otolaryngology entrance hall increased the recognition rate and was installed with two pairs from the ground to the Reader center height of 135cm and 68.5cm, and width of the corridor was 230cm. A desktop type of reader was installed in the nursing room and the tags were recognized by direct contact. In this study, the patient possessed RFID tag is aware of the recognition moment when the installed antennas location and the vision of a box in the form of implementation are listed in the time order, which allows researchers to use estimate pathway of outpatient. In addition, a duplicate tag was recognized by the Reader in order to solve the problem of the the patient's gait speed within 5 seconds and to account for new understanding of the signal recognition results were excluded from the program.

Results

Table 1– Number of RFID detection according to case

	Unable-to-recognize case	Duplicate-check + able-to-estimate location	Able-to-estimate location	Able-to-estimate treatment time
Initial visit	39	123/162 (0.759)	90/162 (0.555)	17/162 (0.105)
Follow-up visit	0	73/73 (1.0)	59/73 (0.808)	14/73 (0.191)
Sum	39 (0.615)	196 (0.834)	149 (0.634)	31 (0.131)

Discussion

Hospital workers are facing a new problem called 'to adapt to change', but in the past when discussing the success of hospital information hardware was the main concern then the software but recently has focused attention on human element This study explored the potential of RFID technology applied to patients in the hospital for the first time, but in the future it may improve the recognition rate with a solution methodology for medical use even in the form of quantitative methods, as well as qualitative analysis research methodology for use in future studies.

Developing an Online Decision Aid for Osteoarthritis

Glenn Salkeld[a], Sally Wortley[a], David Hunter[b], Hema Umapathy[b], Jack Dowie[c]

[a] *School of Public Health, University of Sydney, Australia*
[b] *Institute of Bone and Joint Research and Kolling Institute, University of Sydney, Australia*
[c] *London School of Hygiene and Tropical Medicine*

Abstract

A decision aid for osteoarthritis was developed using the best available evidence on effect size, potential harms and self-rated performance for other attributes. The aid was developed using a multi-criteria decision analytic tool capable of combing evidence and an individual's preferences for the attributes related to treatment.

Keywords:
Decision aid; osteoarthritis; multi-criteria decision analysis.

Introduction

Decision making for osteoarthritis is complex because of marked variations between patients in weight, tolerance for physical activity, and risk for anti-inflammatory adverse events including both gastrointestinal and cardiovascular toxicity. There are also variations between patients in frequent concomitant comorbidities including depression, hypertension and/or diabetes. All of these variations can influence informed osteoarthritis management decisions. This led us to develop an online decision aid as a means of combining the best available evidence on the benefits and harms of osteoarthritis management with patient preferences. The aim of the aid is to provide an opinion on which treatment option may be best for them.

Methods

The decision aid uses a generic web-based decision-support template grounded in multi-criteria decision analysis (MCDA). The app, known as Annalisa© (AL), uses a simple expected value algorithm to calculate a score for each option. The score takes into account the individual's preferences for different criteria (stored as importance weights) and the evidence of the performance of each option on each criterion.

The aid allows for the dual personalisation of the decision in terms of both the clinical characteristics of the patient and their preferences in relation to the benefits and harms associated with the alternative treatment options. It incorporates evidence on both the benefits and the potential harms of a range of osteoarthritis management options (the 'attributes') from published evidence-based guidelines, tailoring these as closely to the specific patient as possible by information elicited about the patient. By combining this evidence with the individual's importance weights for the various outcomes, which is elicited in a graphical way at the point of decision, the best course of action for each patient will be identified on the basis of quantified scores for each option. This poster will present a summary of the systematic review of the literature on both qualitative and quantitative studies reporting on treatment preferences of patients with osteoarthritis. It will also present graphically the design and content of the osteoarthritis decision aid as a work in progress.

Results

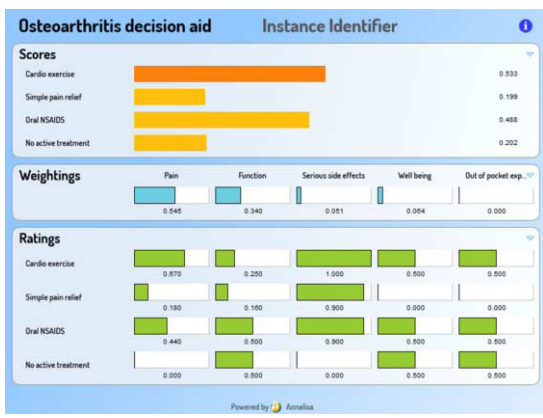

Figure 1 – Osteoarthritis decision aid

The aid will be launched in June 2015 and preliminary results will be available by July 2015. The results from the work in progress will be presented at the conference.

Conclusion

The proposed osteoarthritis decision aid uses the best available evidence to populate the aid based on the options and attributes that the user identifies as being important to them. It is feasible to combine evidence and individual's preferences in a way that provides a quantified score for determining which option is best.

[c] *Department of Computer Science, Stevens Institute of Technology, Hoboken, New Jersey, USA*

Abstract

Examination of the pupil offers an objective evaluation of visual function as well as the vegetative pathways to the eye. This work proposes the development of an effective method and a portable device to test the consensual pupillary reflex. The first results demonstrate the success of a new device construction and methodology to record the consensual reflex with different stimulus, in a situation of complete blockage of light.

Keywords:
Consensual Reflex; Pupillometry; Computer-aided diagnosis.

Introduction

The pupillary inspection is a valuable part of the ophthalmological, neurological and general medical examinations routine [1]. Pupillary examination involves recording the size, symmetry, and light reactivity of both pupils [2].

Materials and Methods

To apply the test methodology, a pupilometer was built based on consensual human optics reflection. The Pupilometer has a lighting system with visible light that gradually goes from 0 (zero) to 38 lux, positioned at a 3 centimeters distance from one of the eyes and completely seals illumination as shown in Figure 1 (a). The four metrics used to test methodology were amplitude, latency, time to maximum contraction (TMC), time to maximum dilation (TMD). Twenty-nine volunteers' participated and 61 records were made, with 1 to 5 recordings for each volunteer. Eight volunteers were females (27.58%) and 21 males (72.41%). Through the software it was possible to set visual stimulus duration, intensity and choose which eye should be recorded.

Results

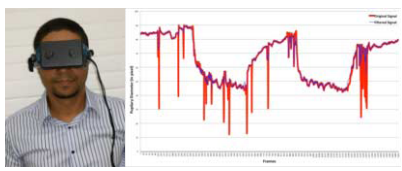
Table 1 shows the mean and standard deviation of the tests performed with 61 videos.

Table 1 – Configuration of visual stimulus

Parameter	1st Period		2nd Period	
	Mean	SD	Mean	SD
Amplitude	0.58%	0.09%	0.59%	0.08%
Latency	0.33 seg	0.57 seg	0.24 seg	0.10 seg
TMC	1.67 seg	0.37 seg	1.57 seg	0.41 seg
TMD	1.84 seg	0.29 seg	1.85 seg	0.27 seg

Discussion

In some cases, the volunteer movements caused failures on pupil segmentation and, therefore, caused noise in the signal. To correct them, the software used the neighborhood average algorithm, resulting in a sign like shown in Figure 1 (b).



(a) (b)

Figure 1 – (a) Volunteer using the pupilometer, (b) Example of the algorithm application by software

Conclusion

The Pupilometer and the software proved to be an effective, non-invasive and portable pupillary behavior after light stimulus identification method, being a useful tool to integrate in the clinical, emergency, ophthalmology and neurology related medical routine. It is necessary to conduct more clinical investigations to determine pathological patterns in patients with diseases. This work can also open a way to new studies involving computer-aided diagnosis (CAD). Changes in the software could make possible studies to identify signs of a probable disease.

A Global Analysis of Approaches to Sharing Clinical Data with Patients

Jennifer E. Prey[a], Fernanda Polubriaginof[a], Gilad J. Kuperman[a,b], Victoria Tiase[b], Sarah A. Collins[c], David K. Vawdrey[a,b]

[a] *Department of Biomedical Informatics, Columbia University, New York, NY, USA*
[b] *NewYork-Presbyterian Hospital, New York, NY, USA*
[c] *Partners Healthcare and Harvard Medical School, Boston, MA, USA*

Abstract

Engaging patients in their care has become a topic of increasing importance, and enabling patients to have access to their clinical data is a key aspect of such engagement. To investigate on an international scale the current state of approaches for providing patients with access to their own clinical information, individuals from 16 countries, across six continents, participated in cross-sectional semi-structured interviews. Interview questions focused on social and cultural influences that affected patient engagement activities, government support for current and planned initiatives, data ownership models, and technical issues. Substantive initiatives for providing information to patients in the majority of countries interviewed are present; however, these initiatives were diverse in nature and stage of implementation. Efforts to improve patient access to data are active on a global-scale. There are many open questions about best practices and much can be learned by adopting an international perspective to guide future implementation efforts.

Keywords:

Personal Health Records; Consumer Health Information; Health Information Technology; Patients; International Perspectives.

Introduction

Around the world, people are being encouraged to participate more actively in their healthcare. While individuals in most countries have been able to obtain copies of their medical records for many years, few regularly take advantage of this opportunity. With the proliferation of electronic health records (EHRs), there is much greater potential for patients to access their information. Providing patients with their clinical data is associated with increased satisfaction, improved patient knowledge, control and self-care, and may result in better health outcomes[1].

Methods

This study was a cross-sectional semi-structured interview survey conducted via telephone or videoconference during November and December 2014. The list of interview participants was created using a convenience method of sampling in which research team members identified individuals around the world who had knowledge of patient data-sharing initiatives in their respective countries. Data from the interviews as well as information from literature review were aggregated and analyzed for themes. Countries were grouped based on similarity of characteristics and compared across themes.

Results

Interviews were conducted with individuals representing 16 countries, across six continents. Respondents reported substantive initiatives for providing information to patients in the majority of countries interviewed. There is considerable variability in the level of maturity, the degree of government involvement, the technical infrastructure, and the plans for future development across the world. As informaticians, we are still in the early stages of deploying patient engagement technologies and have yet to identify optimal strategies in this arena.

Conclusion

The sharing of clinical health information with patients is in varying stages of development around the world. The trend is toward increasing engagement of patients and providing more information, especially electronically. Based on this study it is clear that no one country has 'solved' how to provide patients with access to their clinical information. Countries should leverage the experiences of others as we all move forward in the deployment of these systems. When patients are empowered with access to their own clinical information, they will be able to more actively understand and participate in their care, and with this additional knowledge and motivation, hopefully have improved satisfaction and overall health.

Is Access to eHealth Records Important for Patients? – Opinions of Healthcare Personnel

Isabella Scandurra[a], Ture Ålander[b]

[a] *School of Business, Örebro University, Sweden*
[b] *Department of Public Health and Caring Sciences, Uppsala University, Sweden*

Abstract

Sweden has had significant progress with the the introduction of electronic health records. A pilot county deployed in an eHealth service in 2012, giving access to health records for all of its patients. This eHealth service is, however, a controversial issue. Two surveys were conducted to discover whether healthcare professionals' opinions differ between professionals, and between staff who have had experience with patients using eHealth records and those, to date, who have had none. Experienced nurses found this eHealth service more important for the patients compared to unexperienced nurses outside the pilot county, as well as both semi-experienced physicians.

Keywords:

Electronic Health Records; Healthcare Personnel; Online Systems; Access to Information; Web Questionnaires; eHealth.

Introduction

In Sweden, patients have the right to obtain part of their health record. The national eHealth strategy states that all health records should be accessible via Internet by 2017. Within the scope of an EU-project, Uppsala County Council in November 2012, deployed such a public eHealth service to its 350 000 patients as the first national trial of patient-facing records. Access to "eHealth records" is, however, a controversial issue, as many professionals are concerned about patients reading their record without support from clinicians. Do experiences from the pilot county differ from regions where eHealth records are not yet implemented? This study aims to discover whether healthcare professionals think this eHealth service is important for the patients.

Materials and Methods

This study collected data from two 5-graded Likert scale web surveys of Swedish healthcare staff, focused on attitudes and opinions of physicians (S1) and nurses (S2). S1 was sent out in June 2013 to 1600 physicians in the pilot county with a response rate of 25% (399 respondents). S2 was sent out in March 2014 to 8460 registered nurses and midwifes in Sweden with a response rate of 35,4% (2867 respondents). The questionnaires consisted of background questions and 5 sets of items with free text fields in each set. To deliver the questionnaires, web survey tools were used.

Standard data reports were created for each survey, with charts showing the most prominent differences in each statement. Currently each statement is being analysed by statistics and healthcare informatics researchers and students. As the questionnaires were jointly developed, this first analysis is expected to discover differences between care professionals that have had experience with patients using eHealth records and those working in regions where the service was not yet implemented.

Results

The statement analysed in this study was: "To which extent patients' access to eHealth records is important for the patients?" Responses were stated on a 5-graded Likert scale from strongly disagree [1] to strongly agree [5] and are presented as a percentage, based on 241 nurses in the pilot county, all 2871 other nurses in Sweden, and 387 Physicians in the pilot county. In general, nurses' opinions of patients reading their health record online were neither entirely positive nor negative (median=3), while physicians were generally more negative (median=2).

Table 1 – "To which extent is access to eHealth records important for the patients?"

Professions	1	2	3	4	5
Nurses, pilot county	9	16	37	17	18
Nurses, All other	13	25	35	15	10
Physicians, pilot c.	28	36	27	8	2

Nurses experienced with patients having eHealth records, were more positively (35% agree and strongly agree) inclined towards this service for patients, compared to nurses in the rest of the country (25%) as well as physicians (64% strongly disagree or disagree).

Time between the questionnaires (9 months) introduces uncertainty of comparability between professions' opinions. The differences between experienced and unexperienced nurses were important to observe. The nurses in the pilot county may have experienced that access engenders a positive effect when the patient meets with healthcare providers.

Conclusion

As experienced nurses found this access more important for the patients compared to unexperienced nurses and semi-experienced physicians it is important for development to disseminate these findings to unexperiencenced peers.

Abstract

We designed, constructed, and evaluated a mobile medical care vehicle called "Rollende Arztpraxis" (rolling medical practice, RMP) that delivers the full medical care of a general practitioner to increase medical care supply in rural areas. Six communities have been identified, where the RMP has been visited 501 times in 14 months. Two different schedules of stops and treatment times have been tested. We show that the RMP treated mainly elderly and multimorbid patients. An accompanying study showed high acceptance and satisfaction of treated patients and treating doctors. An economic evaluation of three different utilization models with three treatment modes each showed no financial sustainability. We show that ambulatory care in rural areas can be complemented by a mobile care unit, if legal and financial barriers can be overcome.

Keywords:
Rural Health Services; Mobile Health Vans.

Introduction

The German healthcare system is threatened by a lack of doctors [1]. Similarly affected are all communities in northern Germany regarded in the context of this paper. Respective estimations in [2] with a narrower regional scope show significantly reduced medical supply until 2020. Combined with a growing number of elderly, and therefore, more chronically diseased and multimorbid patients, a rising need for medical supply can be assumed. The main objective of the project is to study if ambulatory care in rural areas can be complemented by a mobile care unit called "Rollende Arztpraxis" (rolling medical practice, RMP).

Methods

We investigated technical feasability over 14 months. An accompanying study is split up into four work packages addressing usage figures, satisfaction of patients, satisfaction of doctors and economic sustainability.

Results

The RMP is a commercial utility van with a custom box and a completely adapted interior for the RMPs' primary use case of ambulatory care. Six low-population-communities (A-F) have been selected as stop and treatment places for the RMP. 501 treatments were made. Patients mainly reached the RMP on foot and by bike. Nearly all patients (n=36) surveyed were "very satisfied" or "rather satisfied" with the RMP as a whole. Resident GPs surveyed believed there was an improvement in medical care. Some GPs reacted rather angrily and found the RMP irresponsible or a solely political instrument. According to the mobile doctors, treatment was without any problems. The RMP contains all technical equipment for the treatment of a broad spectrum of patients; many immobile and some disabled patients have been treated without problems. Since no medical assistant was present at the RMP, all organizational work had to be done by the doctors themselves. This resulted in a maximum of 10 to 12 patients a day.

Conclusion

Our technical feasability evaluation showed that full ranged mobile medical care in rural areas is possible if financially subventioned.

Online Communication and Chronic Obstructive Pulmonary Disease (COPD)

Ina Koldkjær Sølling [a], Per Carøe [a], Kurt Lindgren [b] Kirsten Siggaard Mathiesen [a]

[a] *Department of Nursing, University College of Northern Denmark, Denmark*
[b] *Department of Technology and Business, University College of Northern Denmark, Denmark*

Abstract

This is an explorative and qualitative study that examines a municipal's rehabilitation program "Online Viva" (2014–2015). The questions are whether "Online Viva" improves the citizens' participatory health and whether it prevents exacerbation of COPD. "Online Viva" includes respiratory training and district nursing consultancy for elderly people with COPD. The district nurses' presence in the citizens' homes is replaced by online communication. The study involves 9 citizens and 5 health professionals. Preliminary results show that online consultations and training prevent anxiety, exacerbation, and support the citizens' management of COPD. The citizens find that the "Online Viva" reduces their need for hospitalization, and this is confirmed by the district nurses. Furthermore, the citizens find that their specific needs are fulfilled, making them comfortable in managing their COPD. It is emphasized by the citizens and the district nurses that they must have been in personal contact with each other before they meet online. Furthermore, it must be possible to visit the citizens in their private homes in addition to an online contact, if needed.

Keywords:

Patient centered care, aged care, participatory health, COPD, preventive medicine

Introduction

In 2013, Slagelse Municipality implemented an online rehabilitation program, "Online Viva" with respiratory training and district nursing consultancy for elderly people (aged 61-90) with COPD. In September 2014, 20 citizens with moderate (50%) to severe (15%) reduced lung function were included in "Online Viva", the objective of which was to support the citizens' participatory health and to prevent COPD exacerbation . The intention was to include 30 citizens with COPD or another chronic disease. The demographic development results in more elderly people living longer with chronic diseases, as well as lack of financial resources in the health care sector of the municipalities. There is an assumption that welfare technology can provide cost-effective solutions to the benefit of future citizens despite the strained economy. The technology used in "Online Viva" is based on an online encrypted connection with synchronous video communication. The citizen and the district nurse are able to communicate via the internet at a scheduled time.

Methods

This project is an explorative and qualitative study including 9 citizens (5 women and 4 men aged 62 – 82), 3 district nurses, the supervisor of the project, and the head of the department. Face-to-face semi-structured interviews were conducted with the citizens, the supervisor, and the head of the department. Furthermore, we conducted a focus group interview of the 3 district nurses who provided an audio-reflection about the online consultancy with the citizens (2, 3). In relation to the technology, we chose a socio–technical approach (4). Additionally, we will discus the results with healthy elderly of the DanAge Association (NGO) .to maintain a citizen perspective. The study was approved by the Danish Study of Ethics in Science and Data Protection.

Results

Preliminary results show that online consultations and training prevent anxiety and COPD exacerbation resulting in improved COPD management. . As per citizens' opinion, the "Online Viva" reduces their anxiety and need for hospitalization; confirmed by their district nurses. Additionally, the citizens find that their specific needs are fulfilled making them comfortable in managing COPD. It is emphasized by the citizens and the district nurses that a personal relationship must be established before meeting online. Furthermore, the nurse should be able to visit the citizens in their private homes in addition to an online contact, if needed. The professional knowledge at specialist level and practical experience with technology of the district nurses are necessary requirements for obtaining a confident online communication with the citizens. Furthermore, the district nurse should be able to make decisions, act appropriately, and ensure that the sound and picture are of good quality during online meeting.

Conclusion

The preliminary results indicate that a focused online consultation with respiratory training improves the citizens' participatory health. The consultation and training support the citizens' management of COPD and prevent anxiety, COPD exacerbation, and hospitalization. The district nurse should be well qualified in academic and technological skills and should be able to work at a specialist level.

Development and practice of ISMS at a Radiotherapy Hospital by using IHE Integration profiles

Yutaka Ando[a], Yuki Yoshida[b], Masami Mukai[b], Yasuo Okuda[b], Tadashi Kamada[a], Shuichi Moriguchi[c]

[a] *Research Center for Charged Particle Therapy, National Institute of Radiological Sciences, Chiba, Japan*
[b] *Medical Informatics Section, National Institute of Radiological Sciences,* [c] *MPO Co., Ltd., Yokohama, Japan*

Abstract

Our hospital is specialized for radiation therapy and has many information devices. Various job categories are working. When we implemented an EMR, we aimed to enforce ISMS by using IHE profiles. To solve the already existed system-related problems, we selected and use some profiles (EUA, PSA, ATNA and PAM). After implementation, we audited and then some findings were pointed out. These findings are being settled by the PDCA cycle. We also found that appropriate IHE profiles were effective in the building of ISMS.

Keywords:

ISMS, IHE Integrating the Healthcare Enterprise, PDCA

Introduction

Our hospital is specialized for a radiation therapy with a Carbon ion. We have 100 beds for inpatient, 70-110 outpatients/day and two departments (Radiology and Dentistry). There are many special treatment devices and information terminals in our hospital. And our staff consists of many occupational categories such as physicians, nurses, technicians, operators and clerks. Complexity and diversity of our information system may hold some problems. These problems are: (1) single sign on, (2) synchronizing patient, (3) time consistency and audit log and (4) co-operation among information systems.

The promotion of Information Security Management System (ISMS) is a key issue. We use some integration profiles of Integrating the Healthcare Enterprise (IHE) to improve the security of information system and to solve these problems. We evaluate the IHE profiles in the aspect of security management.

Materials and Methods

We implemented some IHE profiles to solve some clinical problems mentioned above. Methods we used were Enterprise User Authentication (EUA) for single sign in, Patient Synchronized Applications (PSA) for co-operation of same patient, Audit Trail and Node Authentication (ATNA) for audit log, and Patient Administration Management (PAM) for patient information reconciliation. These EUA/PSA functions are protected from misselection of patient and forgotten logout.

In 2006 our hospital had prepared to strengthen information security and we detected the personal information and analyzed the system's risk. Also we had defined regulations concerning handling and protection of personal information.

From 2007 we have continued the audit about our privacy policy and security policy according to what ISMS established. We practiced this audit once per year. The audit result proceeds to the management review of the hospital director. The PDCA cycle consists of Plan, Do, Check and Act. We then executed this cycle (audit, analysis of problems, action plan, manual revise and check list) in a year. These processes are shown in Figure 1.

Results

Audit findings are as follows: (1) An unimproved rule about cancellation of a user account and abolition, (2) A connection of an internal network and the internet, (3) An inadequate periodic supervision and management about practical use of a USB memory, (4) An incomplete key management of the outpatient's examination room, server room, rocker and security chain of the PC body, (5) Insufficiency in the password management and (6) An unclear responsibility of procedure of a wireless LAN and operations management.

The PDCA cycles decreased these problems. Finally at the promotion of ISMS, we feel undoubtedly that these problems have to be solved. They are (1) Improvement of motivation for ISMS implementation, (2) Complexity of risk analysis in a medical field and (3) Difficulty of evaluating the weight of confidentiality, integrity and availability. Hospital staffs were familiar with the PDCA cycle and did not offer resistance to use PDCA cycle. We think that the promotion of ISMS depends on a deep understanding and strong leadership.

Figure 1 – PDCA cycle in our hospital

Conclusion

We implemented EMR and planned to improve information security using IHE profiles. We utilized PDCA cycle to raise information security level. In addition, we believe that when we select the suitable IHE profiles, we can achieve the reinforcement of the secure information system at the hospital information systems.

Optimizing Safety, Fidelity and Usability of an Intelligent Clinical Support Tool (ICST) For Acute Hospital Care: an Australian Case Study Using a Multi-Method Delphi Process

Mari Botti[a], Bernice Redley [a], Lemai Nguyen[b], Kimberley Coleman [a], Nilmini Wickramasinghe[c]

[a]*Epworth HealthCare/Deakin University Centre for Clinical Nursing Research*
[b]*Deakin University School of Information and Business Analytics*
[c]*Epworth HealthCare/RMIT University Health Information Management*

Abstract

This research focuses on a major health priority for Australia by addressing existing gaps in the implementation of nursing informatics solutions in healthcare. It serves to inform the successful deployment of IT solutions designed to support patient-centered, frontline acute healthcare delivery by multidisciplinary care teams. The outcomes can guide future evaluations of the contribution of IT solutions to the efficiency, safety and quality of care delivery in acute hospital settings.

Keywords:

Nursing informatics; patient safety; user-centred design; acute healthcare delivery

Introduction

Technology innovations in medical informatics have transformed many areas within healthcare delivery; however, poor uptake of technology remains a widespread problem. Technology solutions to support clinical work are frequently engineered from administration requirements rather than the needs of front-end clinicians; making them confusing to users, incompatible with existing clinical workflows, increasing workloads and creating potential risks to patients [1-4]. As a result, clinicians often either abandon these systems or are highly resistant to using them.

This study examines the benefits of adopting a user-centred design approach in developing and deploying an intelligent clinical support tool (ICST) in acute clinical settings in public and private hospitals in Melbourne, Australia. The methodological approach designed to address this issue is presented as an appropriate, systematic strategy that mitigates safety risks and enhances the likelihood of user adoption and acceptance.

Methods

The study adopts a multi-method approach using qualitative and quantitative techniques. A key unique feature of the research is the Delphi process used to elicit multi-disciplinary responses and interactions with the system. Critical phases of the methodology include: **Phase 1** - Establish fidelity: Interviews with key multidisciplinary users to explore their specific information needs, interactions, work flow, data inputs and outputs associated with patient care delivery. **Phase 2** – Evaluate fidelity: A Delphi process to examine multidisciplinary agreement on system design for patient safety will include up to six improvement cycles and one consensus cycle over twelve months. Each cycle will incorporate discipline specific data into the ICST and observe participants using the technology in simulated clinical scenarios. 'Think- aloud' [5] techniques will be used to elicit participants' experiences when interacting with the system and interface. **Phase 3** – Reflections on fidelity and safety: Brief interviews with participants at the end of each Delphi cycle. An online survey of system usability and fidelity will be collected one week after each cycle.

Results

The continuous feedback and cyclic improvement of the system provide the possibility to design, develop and deploy a sophisticated clinical informatics solution that caters to the real workflow needs of multidisciplinary clinicians. This serves to ensure superior levels of usability, safety and fidelity for clinical practice, as well as reduces the likelihood of resistance and lack of use of the technology solution. At this stage of this research in progress we are in Phase 1 to establish fidelity. Interviews with key users have enabled us to identify the different user needs and ensure that the solution has the capability to address these respective needs.

Conclusions

To date we have identified commonalities and discipline specific needs to inform system design. This research has far reaching implications for the design, development and deployment of sustainable informatics solutions that ensure the safety of patients while streamlining and improving clinical practice through technological innovation.

[c] *CHU Rennes, CIC Inserm 1414, Rennes, F-35000, France*

Abstract

This work proposes an integrated workflow for secondary use of medical data to serve feasibility studies, and the prescreening and monitoring of research studies. All research issues are initially addressed by the Clinical Research Office through a research portal and subsequently redirected to relevant experts in the determined field of concentration. For secondary use of data, the workflow is then based on the clinical data warehouse of the hospital. A datamart with potentially eligible research candidates is constructed. Datamarts can either produce aggregated data, de-identified data, or identified data, according to the kind of study being treated. In conclusion, integrating the secondary use of data process into a general research workflow allows visibility of information technologies and improves the accessability of clinical data.

Keywords:

Biomedical research; Secondary use of data; Confidentiality

Introduction

With the development of electronic health records (EHRs) secondary use of patient data is becoming a critical issue for medical research. Hospitals are currently deploying information technologies (IT) and tools intended to facilitate easy access to clinical data for research purposes.

In this paper, we present an integrated workflow that aims to manage and to monitor the global process of reusing clinical data for research purposes. This workflow system addresses three main scenarios of clinical research: feasibility study, pre-screening or cohort building, and monitoring. It is currently used and tested by the Clinical Research Office (CRO) of the Academic Medical Centre of Rennes (AMC).

Methods

The workflow is based on two main applications: a research portal dedicated to the research activities in the Academic Medical Centre of Rennes and EHOP, the clinical data warehouse (CDW).

The portal and the information retrieval interface of the CDW were developed as web applications employing the following technologies: Angular.js framework, Java technologies (portal) or php (CDW), Oracle database, and Oracle text functionalities. The system was integrated in the Hospital Information System (HIS).

Results

The goal of the research portal was to give to physicians a platform for any research purposes such as methodology, data analysis, data extraction or the global management of a research project. Each request was primarily treated by the CRO and then assigned to one or more resource experts within each specialized field. Any ticket concerning reuse of patient data were addressed to the experts of the data-mining department of the hospital.

Prior to the granting of physician access to patient data, several requirements were fulfilled. The expert must select from aggregated, de-identified, or identified individual data, the type of access required for the study. Ethical and legal procedures to be followed by the physician were contingent on study-type. The research portal aimed to be a support to assist the physician for theses procedures and to monitor activity.

The next step was to identify the characteristics of the studied population in order to fulfil all the necessary elements to request the CDW for candidate patients.

Access to the entire dataset stored in the clinical data warehouse was limited to experts of the data-mining department. They were responsible for extracting a subset of potential patients (except those who refused to have their data used for research purposes) of interest for the study. Data were then replicated in a datamart and made available for physicians for a limited time through a link available in the study's ticket. Physicians were thus able to mine candidate patients' data to check their eligibility for the study by using Datamart information retrieval tools.

Conclusion

Developing relevant tools to support the reuse of patient data and especially to manage every step of the workflow appears to be crucial. Integrating the secondary use of data process in a general research workflow gives visibility to information technologies and makes access to clinical data easier. Moreover, it allows traceability of access to data and monitoring of activity of secondary use of patient data.

Screening Mammography Efficacy: A Comparison Between Screen-Film, Computed Radiography and Digital Mammography in Taiwan

Dr. Abdallah Ahmed Elbakkoush[a, 1], Suleman Atique [a], DR.I-Jen Chiang [a, 1]

[a] *Graduate Institute of Bio-medical Informatics, Taipei Medical University, Taiwan*

Abstract

Breast cancer screening has been proven effective in Western countries, and our National Health Bureau also started to offer free screening mammography for women aged between 50 and 69, since July 2004. This study aims to compare the efficacy between distinctive mammography screening modalities. Prompting the assessment of digital screening in the radiological sciences, we provide insight into the practical informatics application of such tools.

Keywords:

Computed Radiography; Digital Mammography, Screen Film, Screening method

Methods

Between July 2004 and December 2010, 23513 eligible women underwent screening mammography. 6804 of these received screen-film mammography, 1610 received computed-radiography mammography, and 15099 received digital mammography. The carcinoma-in-situ detection rate, early cancer detection rate, and the overall cancer detection rate of each modality were calculated. Chi-square test was used to determine the statistical significance of performance differences between these modalities. Different modalities, which are derived from informatics applications in the radiological sciences, are compared in this paper.

Results

Screen-film mammography's callback rate was 12.23%, cancer detection rate was 5.29%, and Ductal Carcinoma In Situ (DCIS) detection rate was 1.76%. Computed Radiography's callback rate was 12.67%, with a cancer detection rate of 6.21%, and DCIS detection rate of 1.24%. Full-field digital mammography (FFDM) had the highest callback rate of 9.21%, but also had the highest rate of cancer detection rate and DCIS detection rate, 9.21% and 3.58%, respectively.

FFDM had better cancer detection rate and DCIS detection rate compared to Screen-Film Mammography (SFM) and Computed Radiography (CR), however, this only demonstrated statistical significance when compared to SFM. Although FFDM had better cancer and DCIS detection rates, it was also associated with a higher callback rate. Results show that the employment of digital modalities can enhance the understanding and application of mammography tools in the radiological sciences.

Discussion

The cancer detection rate for Digital Mammography was higher than both SFM and CR Mammography in the screening of breast cancer and ductal carcinoma in situ.

Unlike prior reports, our results show that the incidence rate for Taiwan women is not low. CR mammography had a lower DCIS detection rate, compared with DR, in Taiwan women dense breast. If we rely on CR, we may fail to identify many DCIS cases, which is an important consideration. As the price of DM gradually decreases, by using DM, facilities may save on storage space, retrieval and processing time, and promote a more comfortable environment for patients. In order to improve the efficiency, quality, and safety of patient care, there is need to further explore such tools in the field of radiology.

Conclusion

Full-field digital mammography has obvious performance advantages over screen-film and computed radiography mammography. This is important, especially in Asian populations where the prevalence of dense breasts is increased. Taiwanese breast cancer incidence is gradually increasing and becoming comparable to that of Western countries. Such factors, in addition to Taiwan's unique medicolegal ecosystem, result in relatively high callback rates.

Evaluation of a Cyber Security System for Hospital Network

Mohammad A. Faysel[a]

[a] *Medical Informatics Program, SUNY Downstate Medical Center, Brooklyn, NY, USA*

Abstract

Most of the cyber security systems use simulated data in evaluating their detection capabilities. The proposed cyber security system utilizes real hospital network connections. It uses a probabilistic data mining algorithm to detect anomalous events and takes appropriate response in real-time. On an evaluation using real-world hospital network data consisting of incoming network connections collected for a 24-hour period, the proposed system detected 15 unusual connections which were undetected by a commercial intrusion prevention system for the same network connections. Evaluation of the proposed system shows a potential to secure protected patient health information on a hospital network.

Keywords:

Cyber security; Hospital network; Health information system.

Introduction

Due to recent advancement in health information technologies and mandatory adoption of electronic health records, dependency on the Internet is unavoidable for accessing patient health information [1]. Hospitals are relying on commercially available network security tools such as firewalls, intrusion detection system (IDS), and intrusion prevention system (IPS) to secure information network. These tools have already been proven to be inadequate to defend real-time cyber security incidences [2]. The proposed system utilizes packet header information from incoming network connections and applies a probabilistic data mining technique to detect cyber security incidences in real-time. When an anomalous network connection is detected, it also generates real-time alert messages to the hospital network administrator.

Methods

The cyber security system consists of three modules- a network connection capture module, a detection module, and a response module. The network connection capture module collects incoming IP packet headers generated by perimeter firewalls. It uses Netflow [3], a protocol developed by Cisco Inc., to capture the following fields related to a network connection: source IP address, destination IP address, source port, destination port, TCP Flags, protocol, and time. The detection module utilizes these packet information and applies a probabilistic data mining algorithm to calculate a normality score for each connection [4]. The algorithm uses values of these fields as inputs and compares them to the most recent week's network connections. Then, it calculates a probability score for each of the field based on the presence of the values in the past week's network connections; and assigns a normality score to each incoming connection as sum of these scores. The algorithm then compares this normality score to a threshold (the lowest normality score in the past week's attack free network connections). If a connection score exceeds the threshold, it labels it as an incidence and invokes the response module. It also creates an attack signature based on the incidence. The response module generates alert notification to notify the administrator in real-time for further action.

Results

The system was implemented using MySQL 5.1 database environment. It was evaluated on network connections collected for one day period from a real hospital network. The evaluation dataset consisted of 3,850 unfiltered incoming network connections. The system accurately detected 15 unusual network connections during the evaluation which were visually inspected and verified as anomalous. The results were compared to the system log of a commercial IPS that was protecting the hospital network for the same time period. The IPS was unable to detect those 15 unusual connections which were detected by the proposed system.

Conclusion

The evaluation was done using real network connection from one hospital. The author plans to further evaluate the system on multiple hospital networks in real-time. Based on the evaluation results, the proposed system outperformed the commercial IPS tool in detecting unusual incidences. In addition, it shows a potential to defend cyber security incidences on hospital network.

[f] *Columbia University, NY, USA.* [g] *Partners In Health, Boston, USA*

Abstract

Ebola treatment presents unique challenges for medical records because strict infection control requirements rule out most conventional record-keeping systems. We used the OpenMRS platform to rapidly develop an EMR system for the recently opened Kerry Town, Sierra Leone Ebola Treatment Centre. This system addresses the need for recording patient data and communicating it between the infectious and non-infectious zones, and is specifically designed for maximum usability by staff wearing cumbersome protective equipment. This platform is interoperable with other key eHealth systems in the country, and is extensible to other sites and diseases.

Keywords:

EMR; Ebola; OpenMRS.

Introduction

The 2014 West African Ebola outbreak is unprecedented in its scale and spread, with nearly 20,000 reported cases by December 2014. Ebola Treatment Centres (ETCs) are specialized facilities that must provide efficient care for suspected and confirmed Ebola patients while minimizing risk of cross infection to staff and other patients. This presents several challenges, including the difficulty of working in personal protective equipment (PPE) due to heat and low visibility/dexterity, and the inability to move material from highly infectious patient areas (Red Zone) to low-risk areas (Green Zone). Conventional paper-based data collection is difficult for these reasons. ETCs are therefore often limited in their ability to collect data for care, surveillance, and research.

Important ETC information tasks include medication ordering and monitoring; initial, daily and per-shift patient assessments; lab test ordering and results; and fluid management. These require data entry and review within the Red Zone, as well as communication and coordination between zones. Here, we describe the rapid development of an innovative Ebola EMR system based on the OpenMRS open-source EMR platform [1]. This system is designed specifically to address the usability, workflow and communication problems noted above.

Materials and Methods

We built an Ebola module for the OpenMRS 2.1 platform for the Kerry Town ETC, run by Save the Children with UK government funding. OpenMRS is a widely implemented flexible open-source, modular EMR platform currently used in over 50 low and middle-income countries. We used Agile software development methodology. Detailed gathering of requirements was done with on-site staff, and domain experts provided design input. We rapidly iterated on designs using wireframes and live prototypes.

Results

The first release (Feb. 2015) included patient registration, limited clinical data entry and a comprehensive drug ordering/monitoring system for the Red Zone and pharmacy. We optimized the tablet-based user interface for PPE use with large text and touch targets, minimal typing, a high-contrast colour scheme, and easy selection of items like commonly used drugs. We used core OpenMRS concepts, data structures and functional modules, and added Ebola-specific core concepts to simplify decision support and reporting across ETC sites. The next release included modules for vital signs, clinical assessment and fluid balance. Later steps include coordination with case finding, contact tracing and lab testing.

Conclusions

Careful user design on a flexible platform can rapidly yield EMRs that are well suited to address the unique data challenges in Ebola treatment centers. Our system can be adapted for other ETCs and for future health crises.

Acknowledgments

We acknowledge the support of the OpenMRS community, ThoughtWorks, Inc, and Save the Children International.

The Impact of an Electronic Medical Record on Repeat Laboratory Test Ordering Across Four Australian Hospitals

Andrew Georgiou[a], Elia Vecellio[a], Ling Li[a], Johanna I. Westbrook[a]

[a] *Centre for Health Systems and Safety Research, Australian Institute of Health Innovation, Macquarie University, Australia*

Abstract

In this study we examined the impact of an Electronic Medical Record (EMR) on repeat test rates (i.e., the same test ordered within a specified window of time) for a commonly ordered set of laboratory tests; Electrolytes, Urea, Creatinine [EUC], Full Blood Counts [FBC] and Liver Function Tests [LFT]. The results point to the potential that timely, evidence-based electronic decision support features can have on the efficiency and effectiveness of the pathology laboratory process and its contribution to quality patient care.

Keywords:

Computerised provider order entry, Evaluation studies, Hospital information systems, Laboratories

Introduction

Electronic Medical Record (EMR) systems can include Computerised Provider Order Entry (CPOE) functionality, and provide for hospital-wide integration of electronic clinical and patient databases. In this study we examined the impact of an EMR on clinician laboratory test ordering patterns by comparing paper and EMR repeat test rates (i.e., the same test ordered within a specified window of time) for a commonly ordered set of laboratory tests (Electrolytes, Urea, Creatinine [EUC], Full Blood Counts [FBC] and Liver Function Tests [LFT].

Material and Methods

Laboratory data were extracted for the period of Aug/Sep 2008-2011 across four hospitals serviced by a single pathology laboratory service. The EMR was initially based on the Cerner PowerChart system Version 2007.16, and upgraded in May 2011 to Version 2010.02.16. The Laboratory Information System (LIS) was the Integrated Software Solutions (ISS) Omnilab v9.4.2 SR10 system. The electronic ordering system presented clinicians with information about previous test orders and results, and alerted clinicians when a repeat test was ordered within 24-hours of the previous test. Ethics approval was provided by the relevant Local Health District Human Research Ethics Committee (HREC: Project No. 11/146) The project was funded by an Australian Government Department of Health: Quality Use of Pathology Program grant.

Results

Overall, for all the data collected, the percentage of repeat tests (which were ordered using either the EMR or paper) was 77.2% (136644/177096) for EUC, 75.1% (126070/167791) for FBC and 68.9% (68953/100019) for LFT. The results show significant ($p<.0001$) reductions in repeat test rates within 1 hour following the introduction of the EMR. Tests for EUC decreased by 0.2% for EUC, 0.1% for FBC and 0.2% for LFT. For repeat tests within 12 hours, there were significant ($p<.0001$) decreases in EMR repeat orders of 1.1% for EUC and 1.2% for FBC. There were also significant ($p<.0001$) decreases of 1.8% for both EUC and FBC repeat tests within 24 hours. For LFT the EMR repeat test order rate increased significantly ($P<.0001$) by 1.8% within 24 hours and 4% with 36 hours. These results indicate a greater concordance with best practice guidelines.

Conclusion

Our results confirm previous evidence about the impact of the EMR on the rate of redundant or unnecessary tests [1,2]. Such improvements are connected to EMR's ability to provide clinicians with an overview of existing test orders for each patient along with a visual aid alerting them to repeat tests undertaken within a "too-short" re-test interval. Taken together these features can enhance clinicians' ability to monitor and regulate their test ordering practices.

Implementation of Data Driven Heart Rate and Respiratory Rate Parameters on a Pediatric Acute Care Unit

Veena Goel[a,b], Sarah Poole[b], Alaina Kipps[a,b], Jonathan Palma[a,b], Terry Platchek[a,b], Natalie Pageler[a,b], Christopher Longhurst[a,b], Paul Sharek[a,b]

[b] *Stanford University School of Medicine, Palo Alto, CA*

Abstract

The majority of hospital physiologic monitor alarms are not clinically actionable and contribute to alarm fatigue. In 2014, The Joint Commission declared alarm safety as a National Patient Safety Goal and urged prompt action by hospitals to mitigate the issue [1]. It has been demonstrated that vital signs in hospitalized children are quite different from currently accepted reference ranges [2]. Implementation of data-driven, age stratified vital sign parameters (Table 1) for alarms in this patient population could reduce alarm frequency.

Keywords:
Clinical Alarms; Vital Signs

Methods

This is a prospective study of alarm frequency after bedside monitor implementation of age stratified data-driven heart rate (HR) and respiratory rate (RR) parameters on a cardiac medical/surgical step-down unit at a quarternary-care children's hospital. The data-driven parameters were derived using nurse-documented HR and RR vital signs (62,508 unique measurements) of all non-ICU hospitalized patients <18 yrs during calendar year 2013 at Lucile Packard Children's Hospital Stanford (LPCH). Alarm frequency data was analyzed over 28 day periods before and after the intervention on 10/27/14. HR and RR alarm data were obtained from the LPCH clinical data warehouse, which stores real-time central monitor system data.

Results

In the pre-intervention study period, there were a total 7,028 HR alarms and 8,400 RR alarms, yielding an average of 14.1 HR alarms/patient day and 16.9 RR alarms/patient day. In the post-intervention period, total HR alarms decreased to 4,844 (9.6/patient day), but RR alarms increased to 20,860 (41.3/patient day).

Discussion

While the frequency of HR alarms decreased following implementation of age-stratified, data-driven vital sign parameters, the frequency of RR alarms markedly increased, particularly for low RR values (*Figure 1*). Factors contributing to this discrepancy might include: (1) inaccurate creation of data-driven parameters because nurse-charted values were used to calculate them rather than raw monitor data, or because representative patients who spent time in the ICU were excluded from the analysis; and (2) it is possible that pre-intervention monitor parameter settings did not represent pre-intervention reference ranges and so when default monitor settings were updated as part of the intervention, the alarm rate increased as a result of this discrepancy.

Conclusion

Our results suggest that adoption of data-driven values for HR alarm parameters will decrease the frequency of HR alarms in a children's hospital. However, further work to understand the increase in RR alarms is necessary, highlighting the challenges in creation and implementation of data-driven vital sign parameters to reduce alarm fatigue.

Table 1– Data-driven HR and RR limits, by age

Age	Low HR	High HR	Low RR	High RR
<1month	<115	>170	<30	>60
1- <6mo	<105	>170	<20	>55
6mo- <1yr	<100	>165	<20	>45
1- <2yr	<90	>165	<20	>45
2- <3yr	<85	>155	<18	>40
3- <5yr	<75	>155	<16	>35
5 -<9yr	<70	>140	<16	>30
9- <12yr	<65	>130	<14	>30
12- <15yr	<60	>125	<14	>30
≥15yr	<60	>115	<13	>25

Application of Barcoding to Reduce Error of Patient Identification and to Increase Patient's Information Confidentiality of Test Tube Labelling in a Psychiatric Teaching Hospital

Hsiu-Chu Liu[a & b], Hsing Li[b], Hsin-Fei Chang[b], Mei-Rou Lu[b], Feng-Chuan Chen[c]

[a] *EMBA Student, National Pingtung University of Science and Technology, Taiwan*
[b] *Department of Nursing, Kaohsiung Municipal Kai-Suan Psychiatric Hospital, Taiwan*
[c] *Informatics office of Planning Department, Kaohsiung Municipal Kai-Suan Psychiatric Hospital, Taiwan*

Abstract

Learning from the experience of another medical center in Taiwan, Kaohsiung Municipal Kai-Suan Psychiatric Hospital has changed the nursing informatics system step by step in the past year and a half . We considered ethics in the original idea of implementing barcodes on the test tube labels to process the identification of the psychiatric patients. The main aims of this project are to maintain the confidential information and to transport the sample effectively. The primary nurses had been using different work sheets for this project to ensure the acceptance of the new barcode system. In the past two years the errors in the blood testing process were as high as 11,000 in 14,000 events per year, resulting in wastage of resources. The actions taken by the nurses and the new barcode system implementation can improve the clinical nursing care quality, safety of the patients, and efficiency, while decreasing the cost due to the human error.

Keywords:

Barcoding; Identification; Confidentiality; Psychiatric Nursing; Inpatients; Health Care Quality; Technology Acceptance

Introduction

Under the supervision of the city health department and accreditation, the psychiatric teaching hospital needed to improve its nursing informatics system. The new barcode system was influenced by psychiatric patients' right. Double identification of the patients is important to ensure that the staff do not make a mistake of performing wrong test on the patients. However, the psychiatric patients could be uncooperative to the examination and may be unwilling to give the staff their identification information.

Materials and Methods

The questionnaire with experts' validity will be a resource to understand patients' protection, technology acceptance, and satisfaction of the nursing staff. The experts' questionnaire will check Cronbach's α reliability and modify the structured questionnaire to the most streamlined version in two 50-bed acute wards with 30 nursing participants.

The before and after the implementatopm comparison will show the extent of improvement by the barcode system. The acceptance of the nursing staff will also be collected by the questionaire, and the corresponding analysis using the SPSS 17.0 software will assess the usefulness and the ease of use of the barcode system.

Results

We expect that this project will 1) decrease the number of errors in the psychiatric patients' blood test processing, and 2) improve the understanding of the factors related to the acceptance of barcode system.

We appreciate Kaohsiung Chang Gung Memorial Hospital for providing the barcode system used in the general settings for target learning. We also like to thank superior management officers for their continuous support.

Open Source Software For Patient Data Management In Critical Care

Jacques Massaut[a,b,c], Nicolas Charretk[b,c], Olivia Gayraud[c], Rafael Van Den Bergh[c], Adelin Charles[b], Nathalie Edema[b]

[a] *Intensive Care, Brussels Free University, Brussels, BELGIUM*
[b] *Tabarre Trauma Center, Port Au Prince, HAITI*
[c] *Médecins Sans Frontières OCB*

Abstract and Objective

We have previously developed a Patient Data Management System for Intensive Care based on Open Source Software. The aim of this work was to adapt this software to use in Emergency Departments in low resource environments. The new software includes facilities for utilization of the South African Triage Scale and prediction of mortality based on independent predictive factors derived from data from the Tabarre Emergency Trauma Center in Port au Prince, Haiti.

Keywords:

Critical Care, Patient Data Management Software, Open Source Software, Patient Triage Systems.

Introduction

The system for Intensive Care (IC) was designed using a client-server architecture, running on a PostgreSQL database. It offers functions for medical notes, observations and treatments, a scoring system for classification, and reporting of evolution. The system includes utilities for nursing charts and medication administration. To be used in an Emergency Department (ED), the system had to be adapted, particularly to facilitate triage at admission and to propose an adapted score.

Methods

The software was extended to the use of the South African Triage Scale (SATS)[1] and of the TRISS scoring system using the same software architecture as before. For mortality predictions using TRISS, computations were based on the data published by Boyd *et al*[2]. For the SATS system, we did not find any existing publications reporting mortality prediction. To determine mortality prediction, we decided to use data from patients admitted to the Tabarre Emergency Trauma Center from Médecins Sans Frontières (MSF) in Port au Prince, Haiti, as the modified software was intended to be used there. Data from 4,468 consecutive patients admitted to that institution from 01/01/2013 to 08/03/2014 were used. Age of the patients, motif of admission according to MSF classification, and triage category (Red, Orange, Yellow, Green) according to the SATS system were extracted from the local MSF database and used as candidate parameters for analysis of factors associated with mortality. For the statistical analysis we used the Chi Square and Mann-Whitney tests as appropriate to determine association with mortality, and logistic regression with logit to compute independent odds ratios and predict mortality. A p-value < 0.05 was considered to be significant. For logistic regression we divided patients in two groups at random. The first group was used for the computations of odds ratios and coefficients and the second for validation of the model. The STATA 8 software for Windows was used for the statistical analysis.

Results

Added modules to the software help for triage at admission in the ED, and for data encoding. Software includes procedures to compute mortality predictions based on the SATS and TRISS systems. The model included for the SATS system is based on data from Tabarre. Mortality varied significantly with age of the patients, motif of admission, and triage category. Odds ratios for factors affecting mortality with coefficients of logit estimates for that model are illustrated in Table 1.

Table 1 – Factors affecting mortality

Factors	Odds Ratios	Coef.	Z	P > z
Age > 45	2.62	0.963	2.52	0.012
Red	78.98	4.369	7.54	0.000
Orange	3.67	1.300	2.18	0.029
Non Trauma	6.80	1.916	3.56	0.000
(Constant)		-6.317	-11.58	0.000

Area under the ROC curve is 0.8758 for the first group and 0.8344 for the validation group. In the validation group 98.3% of the admitted cases were correctly classified (cutoff of 0.5). In the studied population, the overall mortality was 1.68 %, the mortalities for the SATS groups were 15.81% in the Red group and 1.39% in the Orange. Mortality for patients older than 45 years was 3.29%, versus 1.33% for younger patients.

Conclusion

Our software was extended for the use in the ED, and includes mortality prediction based on the South African Triage Scale. It should now be tested in ED and IC in low resource environments with extension of the data set used in the model.

Measuring ICTs Adoption in Health Care Facilities in Uruguay

Cecilia Muxí[a], Juan Gil[a], Elisa Martínez[a], Betania Arispe[a], Rossana Occhiuzzi[a], Juan Lozano[a], Jorge Forcella[a]

[a] *Salud.uy Program, eHealth National Initiative, Montevideo, Uruguay.*

Abstract

The use of Information and Communication Technologies (ICTs) has gained an important role to enhance healthcare systems by increasing access to services, and improving the quality and equity of care. In order to evaluate the stage of ICTs adoption in the Uruguayan healthcare system, the Governmental Salud.uy Program carried out a national survey to establish the baseline for ICTs adoption, as well as define a set of indicators so as to evaluate the progress on this topic. Data was recorded following the OECD methodology.

***Keywords*:**

ICTs adoption; healthcare system; maturity assessment.

Introduction

The Uruguayan health reform (2007) aimed to increase equity in access and focus on transparency, efficacy and efficiency to improve quality of care through the creation of a National Health Insurance System. ICT serve as the tool to contribute to health services to interoperate and to decrease the health care system's high degree of fragmentation. Due to the lack of complete data and the need of a national analytic maturity assessment tool, the Program carried out a survey in order to measure progress in ICT adoption.

Methods

The survey was carried out from March to June 2014. Two scenarios were considered: healthcare professionals and health institutions. Physicians and nurses registered in the Ministry of Health database were considered for the 600 individuals sample, stratified by professional category. Data was collected by means of two structured questionnaires, following the OECD Guide [1] and the Cetic.Br regional adaptation model [2].

Results

***Technology management and connectivity**:* 100% of the surveyed institutions have internet connection and a website, 71% have an IT area, and 61% have access to their internal network from every place of the facility.

Infrastructure and availability: 6 out of 10 healthcare providers already conduct some part of the clinical health record in a digitalized format.

ICTs availability for health professionals: The analysis concludes that 98% use a computer at home and 96% have internet access. In addition to this, 50% always use a computer at their working place. Perception of a positive potential impact in the reduction of medical errors, patient adherence to treatment, waiting lines and services waiting lists is less than 60%. However, there is an overall positive perception (70%) on how ICTs impact on the efficiency and service quality improvement, as well as the quality of care as a whole.

Barriers to adoption: The two main barriers identified that can constrain EHR´s adoption were: information security confidentiality (55%), and usability features of EHR (52%).

Discussion

Availability of management and administrative data is higher than clinical information availability. However, clinical information is more commonly used by healthcare professionals. The main results showed that there is a favourable context to advance the use of ICTs in the Uruguayan healthcare system.

Conclusion

Despite measured improvements in ICTs application at health institutions, there are still having challenges and barriers to face the EHR´s adoption at national level. Nevertheless, there would be a promising environment and both a political and technological enabling context for the health sector to successfully implement EHR in Uruguay.

Syntactic and Semantic Errors in Radiology Reports Associated With Speech Recognition Software

Michael D. Ringler[a], Brian C. Goss[a], Brian J. Bartholmai[a]

[a] *Department of Radiology, Mayo Clinic, Rochester, MN, USA*

Abstract

Speech recognition software (SRS) has many benefits, but also increases the frequency of errors in radiology reports, which could impact patient care. As part of a quality control project, 13 trained medical transcriptionists proofread 213,977 SRS-generated signed reports from 147 different radiologists over a 40 month time interval. Errors were classified as "material" if they were believed to alter interpretation of the report. "Immaterial" errors were subclassified as intrusion/omission or spelling errors. The proportion of errors and error type were compared among individual radiologists, imaging subspecialty, and time periods using χ^2 analysis and multiple logistic regression, as appropriate. 20,759 (9.7%) reports contained errors; 3,992 (1.9%) contained material errors. Among immaterial errors, spelling errors were more common than intrusion/omission errors (P<.001). Error proportion varied significantly among radiologists and between imaging subspecialties (P<.001). Errors were more common in cross-sectional reports (vs. plain radiography) (OR, 3.72), reports reinterpreting results of outside examinations (vs. in-house) (OR, 1.55), and procedural studies (vs. diagnostic) (OR, 1.91) (all P<.001). Dictation microphone upgrade did not affect error rate (P=.06). Error rate decreased over time (P<.001).

Keywords:

PowerScribe, quality control, radiology report, report errors, speech recognition.

Introduction

Speech recognition software (SRS) decreases report turnaround time, but also increases the frequency of semantic and syntactic errors (1). Such errors may negatively impact clinical management, and result in lawsuits (2). We aimed to analyze percentages and types of errors among speech recognition software–generated radiology reports as part of our quality control program.

Materials

We retrieved transcriptionist audits of all speech recognition software–generated radiology reports (PowerScribe; Nuance Communications, Inc.) that were self-edited and signed by 147 different radiologists, between January 3, 2011, and April 16, 2014. 13 trained medical transcriptionists with 1-23 years of experience proofread a random 5% sample of each radiologist's reports each month. Errors were classified as "material" if the transcriptionist could not readily determine the intended meaning in the context of the report. Otherwise, "immaterial" errors were subclassified as intrusion/omission or spelling errors. Reports with multiple errors were only counted once and classified by most egregious error type (material>intrusion/omission>spelling). Punctuation errors were ignored. The proportion of errors and error type were compared among individual radiologists, imaging subspecialty, and time periods using χ^2 analysis and multiple logistic regression, as appropriate.

Results

Of 213,977 reports identified, 20,759 (9.7%) had errors; 3,992 (1.9%) contained material errors. Among 16,767 immaterial errors, spelling errors (10,151, 60.5%) were more common than intrusion/omission errors (*P*<.001). Proportion of errors and fraction of material errors varied significantly among radiologists and imaging subspecialties (*P*<.001). Errors were more common in cross-sectional reports (vs. plain radiography) (OR, 3.72), reports reinterpreting results of outside examinations (vs. in-house) (OR, 1.55), and procedural studies (vs. diagnostic) (OR, 1.91) (all *P*<.001). Dictation microphone upgrade did not affect error rate (*P*=.06). The total error rate also decreased over the 40-month period of this quality control project by 4.3% (*P*<.001).

Conclusion

Speech recognition software–related errors are highly variable among radiologists and imaging subspecialties. One factor may be length of the report. We calculated a relative risk of error in a cross-sectional report of 3.4 (compared to xray),which is consistent with others (3), though we did not specifically track length. Spelling errors are the most common type of immaterial error in self-edited reports, suggesting many radiologists prefer typing over SR. A quality control program with regular feedback may reduce errors over time.

Diagnostic Imaging Integrated Network: A Teleradiology Pilot in Public Hospitals in Uruguay

Lilian Acosta[a], Karime Ruibal Faral[a]

[a] *Salud.uy, AGESIC, Uruguay*

Abstract

A network of health care centers allows radiologists to share diagnostic images in different areas of Uruguay. This solution is based on an informatics multicenter application for center management, enabling the creation, storage and distribution of images and reports from different imaging modalities according to outsourcing agreements. The solution improves health care territorial equity and reduces asymmetry in resources distribution.

Keywords:

Imaging network; Teleradiology.

Introduction

In 2013 Salud.uy Program designed a pilot project for Teleradiology implementation in Uruguay, developed jointly with an informatics company (MEGA-DATASEC). The Diagnostic Imaging Integrated Network (RIDI in Spanish) was launched in 2014 and aimed at providing a management system for imaging departments and allowing the exchange of imaging studies between healthcare centers.

Methods

The project was conducted in four public hospitals across the country, selected by the Public Health Providers Network (RIEPS in Spanish) [2]. The number of inhabitants, resource complexity and availability of staff in the location were considered. Salud.uy Teleradiology pilot is a system of components and subcomponents of varying degrees of complexity of information hosted on a "cloud". Four components are essential to its goal of achieving a consistent and safe solution for outsourcing images between different centers:

1. Radiological Information System (RIS) as a Policy Enforcement Point -a "door" to the Teleradiology platform- in a Cross-Enterprise Document Sharing (XDS) environment,
2. Administrator Users and Groups for access control,
3. a Picture Archiving and Communication System (PACS) encapsulated in the RIS and
4. a multifunctional proxy appliance or PCS (Picture Communication System) connecting Red.uy network to each local network.

The solution combines a report editor with a web-based viewer for image display and templates of reports according to medical image protocols. The reports are stored in Clinical Document Architecture (CDA) encapsulated in standard Digital Imaging and Communications in Medicine (DICOM) objects [3] to allow future integration with Electronic Medical Record (EMR) and Oncology Electronic Medical Record of Uruguay (HCEO in Spanish) in an IHE XDS environment [4]. In addition, regular monitors were installed in different clinical departments at each hospital, in order to reduce the use of hardcopies. Health professionals and administrative staff were duly trained before RIDI installation.

Results

In Phase 1, RIDI was installed in two centers (the capital and a small provincial city) in September 2014. During Phase 2, two other centers (small provincial cities) are in the process of installation. All centers share the same information management solution (RIS) coupled to a repository (PACS) using a platform for data traffic (Red.uy). RIDI is an open source solution based on interoperability standards and is configured according to the requirements of each hospital. The workflow created by this application impacts the way of working at the imaging department. During the implementation process, resistance to change was detected from the beginning in some of the centers and is currently being solved by providing information, continuous training opportunities and improving usability. Since the project is still in progress, the resulting data are not yet available.

Conclusion

This innovative project allows imaging services in Uruguay to develop collaborative work between centers and at the same time improve each organization. Less patient transfers and shorter waiting times as well as optimization of resources and staff availability across the country enables access to better health services. RIDI also improves doctor-patient relationship by ensuring data safety and confidentiality. Successful development of outsourcing across the country will depend on formal agreements among centers. Furthermore, this project increases and strengthens the sustainability of the National Healthcare System [5]. Finally, once fully achieved, this solution will be made available as a public software.

First Step to Big Data Research in Hospital

Yongdon Shin[a], Changmin Choi[a,b], JaeHo Lee[a,c,d], Soo-Yong Shin[a,d]

[a] *Office of Clinical Research Information, Asan Medical Center, Seoul 138-736, Korea.*
[b] *Department of Pulmonary and Critical Care, Asan Medical Center, University of Ulsan College of Medicine, Seoul 138-736, Korea.*
[c] *Department of Emergency Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul 138-736, Korea.*
[d] *Department of Biomedical informatics, Asan Medical Center, Seoul 138-736, Korea.*

Abstract

Hospitals have accumulated large amounts of data driven by hospital information system such as EMR, PACS, CPOE, and LIMS. While most data are stored in hospital systems, researchers have still experienced trouble to use clinical data. To overcome this problem and promote "big data" research, clinical research information system is necessary. Here an example of such a system, ABLE (Asan BiomedicaL research Environment), will be introduced.

Keywords:

Clinical Research; Information Retrieval System; Hospital Information System

Introduction

As a lot of information from computer or mobile devices has been produced, "big data" has been highlighted due to its promising economic value. Big data does not only mean collecting a big amount of data, but also investigating meaningful information from the data. To promote big data research in hospitals, researchers should be able to easily search for and extract the necessary clinical data from a Hospital Information System (HIS) to find new information. To utilize hospital clinical data more powerfully in the research sector, we built a research information system called Asan Biomedical research Environment (ABLE).

Methods

ABLE was developed over 6 months (from June, 2013 to December, 2013) by collaborating with Inbrein Co. and Microsoft (MS). The MS .Net framework was used to implement ABLE, and the MS Analytics Platform was chosen as the data warehouse appliance. To build a big data platform, we first carefully chose the research data from HIS. Second, we developed a research data server without building a data mart, since data marts are hard to design and maintain as legacy systems change. Next, legacy data were migrated to the research system by the ETL and Change Data Capture (CDC) processes. Finally, we developed three tools: cohort discovery tool, anonymized chart review tool, and data extraction tool.

Results

The cohort discovery tool is used to determine how many patients in a hospital satisfy the inclusion and exclusion criteria. Anonymized chart review tool supports review of each patient's clinical data by removing personal health identifiers [1]. The data extraction tool supports download of the necessary data in Excel format.

Table 1 is a brief summary of the size of data in ABLE. The number of images seems to be smaller than other clinical data since only CT and MRI images were included in ABLE. Those images are easily de-identified using Digital Imaging and Communications in Medicine (DICOM) protocol. We are developing a new method to de-identify non-DICOM medical images such as sonogram and endoscopy images.

Table 1– The brief summary of data in ABLE

Contents	Size of data
Total registered patients	More than 4M
Total Orders	More than 677M
Total medication	More than 202M
Total laboratory results	More than 740M
Total clinical notes	More than 268M
Total images	More than 22M

Since the launch of ABLE (March, 2014), 239 users accessed ABLE and 4,232 queries were executed per month on average. Before the development of ABLE, researchers requested research data from the office of clinical information. There were about 1,800 data extraction requests per year, and it required 3 - 15 days for researchers to receive the data. However, researchers can search and extract the necessary data on one's own desktop using ABLE. As a result, the total number of data requests was reduced to about 1,390 in 2014.

Conclusion

By implementing ABLE, which follows the research process (i.e., cohort identification, chart review, and data extraction) and protects patients' privacy by removing identifiable information, researchers can easily design research hypotheses, review clinical data while protecting patient's privacy, and extract the necessary data quickly and easily. Therefore, clinical research information systems such as ABLE can be a first step to support big data research in hospitals.

Implementing Georeferencing in the Decision-Making Process of a Health Care Provider in Uruguay

Elizabeth Silva Layes[a], Fernando Morales[b], Julio Leivas[a,b]

[a] *Department of Computing, Sociedad Médico Quirúrgica de Salto, Salto, Uruguay*
[b] *Department of Health Statistics, Sociedad Médico Quirúrgica de Salto, Salto, Uruguay*

Abstract

Proper management of information is not only essential but also critical in any organization's decision making process. Data integration and spacial visualization are the key features of georeferencial systems, which bring support to decision making in epidemiology as well as sanitary planning.This paper shows the development of a georeferential system that interacts with the data provided by the Health Care System.Thereby allowing creation of viable methods which will help to improve patient care, treatments, and interventions through building space-time relationships.

Keywords:

Epidemiology; Georeferencing; Decision support systems.

Introduction

The link between epidemiology and planning of health systems and services is considered of superlative importance. Implementation of such a system becomes essential when meeting the needs and demands of the population through the collection, processing and analysis of data [1]. This will describe the health status of the population and its temporal trends, singling out individuals at risk.

Methods

The application has been developed using a Powerbuilder platform as well as google maps for the first tests of georeferencing.

The user selects the type of analysis to perform, and then sets the values of the variables related to the proposed study. The patients who meet the established criteria will be marked on the map. If required, the system will allow navigation through the patient's EHR, only permitted by security controls.

Results

The developed system allows the visualization of spatial and temporal relationships. The system takes into account different kinds of variables, such as health, socioeconomic, financial and demographic, revealing interrelationships between these variables that help in data analysis.

The system can also support decision making processes in epidemics detection; planification programmes aimed to prevent, carry out surveillance, monitor illnesses and identify potential locations for new health care installations, for example.

Figure 1 shows the results obtained after haven selected female patients with tumors (neoplasms), aged 45 to 64 years, located in the city of Salto, Uruguay for analysis .

This application facilitates the visualization of the location of patients and their associated diagnoses, highlighting the geographic areas of highest incidence.

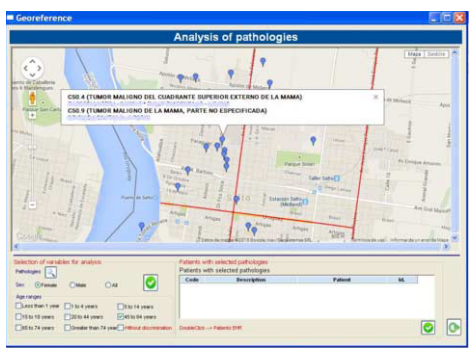

Figure 1 – Female patients with tumors (neoplasms), between 45 and 64 years.

Conclusions

Georeferencing is an important aspect in the study of epidemiology, allowing analysis of geographical and temporal distribution of health events and diseases.

Today it is considered an essential tool, not only in analysis of information for epidemiological decision-making, but also to properly manage various resources in a health care organization. In this sense, the developed application allows analysis of different scenarios through inclusion of multiple variables.

A Development of Automatic Audit System for Written Informed Consent using Machine Learning

Hitomi Yamada[ab], Tadamasa Takemura[b] Takahiro Asai[b], Kazuya Okamoto[c], Tomohiro Kuroda[c], Shigeki Kuwata[a]

[a] *National Cerebral and Cardiovascular Center, Suita, Japan*
[b] *Graduate School of Applied Informatics, University of Hyogo, Kobe, Japan*
[c] *Division of Medical Information Technology and Administration Planning, Kyoto University Hospital, Kyoto, Japan*

Abstract

In Japan, most of all the university and advanced hospitals have implemented both electronic order entry systems and electronic charting. In addition, all medical records are subjected to inspector audit for quality assurance. The record of informed consent (IC) is very important as this provides evidence of consent from the patient or patient's family and health care provider. Therefore, we developed an automatic audit system for a hospital information system (HIS) that is able to evaluate IC automatically using machine learning.

Keywords:
Medical Chart, Automatic Audit System, Machine Learning.

Introduction

Medical records provide evidence to protect both patient and health care worker's rights [1]. Informed consent (IC) is important as it provides evidence of the health care worker's obtaining patient consent, which is critical to health care. If health care workers cannot agree about their care in practice, they faced a heightened risk. The health care workers have to record their agreement in just proportion and hospital administrators have to audit said records in order to protect their mutual interests. It is important to audit patient medical record records to verify written IC has been obtained. However it is very difficult to audit all electronic medical records by humans alone. Therefore, we discussed the possibility of an automatic audit system in order to quality check the medical records for IC using a machine learning technique [2].

Materials and Methods

First, we extracted 298 electronic IC charts from HIS at the National Cerebral and Cardiovascular Center (NCVC) in Japan. At this facility, all medical documentation is elecronically recorded into the HIS by health care workers. A health information manager evaluated the IC documents in five levels from an expert point of view. Next, we considered what level was adequate for IC content, and we determined upper level 3 was adequate quality and lower level 2 was not. We did morphological analysis in Japanese using a medical dictionary to detect specific medical terms in the IC charts. We also used medical words and word numbers as training examples for machine learning. Concretely, we used support vector machines (SVM's) for supervised learning models to be able to mark IC documents as belonging to one of the two categories. At this time, the system determined whether the IC document was a lower level 2 or not.

Results

We evaluated this system by cross-validation. Specifically, we evaluated this system using leave-one-out validation (LOOCV). Consequently, this system could evaluate the IC documents 89.4% (261/292) correctly. The false negative rate was 29% (16/56) and false positive rate was 6.4% (15/236) in determing the lower level 2 IC charts.

Conclusions

A quality review of IC documents is very important in order to protect health care worker and patient rights. The results of this research suggest a possible benefical effect of our automated method utilizing SVM and machine learning. In addtion, we have not adjusted parameters of the SVM yet so it is still possible that this system will learn more data. Additional improvements to this system will need to be made for clincal practice.

Service Quality: A Main Determinant Factor for Health Information System Success in Low-resource Settings

Binyam Tilahun, Fleur Fritz

Institute of Medical Informatics, University of Münster, Germany

Abstract

With the increasing implementation of different health information systems in developing countries, there is a growing need to measure the main determinants of their success. The results of this evaluation study on the determinants of HIS success in five low resource setting hospitals show that service quality is the main determinant factor for information system success in those kind of settings.

Keywords:

Service quality, Low-resource settings, IS success, Evaluation

Introduction

Information system (IS) success measurement is a topic of substantial research and debate. A number of researchers have derived various models to explain what makes IS successful and how to measure it [1, 2].

Among them, the Delone and Maclean Model (D&M) is regarded as the most used and appropriate way to measure IS success by many researchers [1]. The basic dimensions in this model are: system quality, information quality, service quality, system use, user satisfaction and net benefit. The model assumes that those constructs are interrelated and interdependent. Among those factors, user satisfaction is regarded as a primary determinant to measure IS success [3].

With the increasing implementation of health IS in developing countries, it is necessary to identify the main determinant factors as an input for policy making and priority setting. Given that in those settings there is usually limited infrastructure available, it is necessary to assess the quality of internal and external service support for proper use of the system. In this paper our objective is to assess the effect of service quality on user satisfation and hence on IS success.

Methods

Service quality from D&M is operationalized as " the quality of the infrastructure and IT desk support in the hospitals". To measure this, we developed a questionnaire based on the validated five dimensions of SERVQUAL [4]. Additionally, we added setting specific questions like power interruption.

The data collection was part of a hospital IS evaluation study among health profesionals in five public hospitals in Ethiopia. The data collection was conducted from January to February, 2014 .

Results

Out of the 422 participants in this study, 406 (96%) completed the questionnaire. The mean age of the participants was 34 years (±8.5). 217 (53.2%) were males and the majority of the participants were nurses 176 (43.3%), followed by physicians 83 (20.4%) and HMIS staff 74 (18.2%). 190 (61%) of the health professionals reported overall dissatisfaction with the EMR (Median=4, IQR=1) on a five-level Likert scale. Physicians were more dissatisfied (Median=5, IQR=1) as compared to nurses (Median=4, IQR=1) and HMIS staffs (Median=2, IQR=1).

The respondents indicated disagreement with service quality of the implemented system with an overall median score in the range of "Disagree" (Median=4.5 IQR=1.5). The logistic regression shows a strong correlation between service quality and satisfaction - those profesionasl who belive the service quality is good are eight times (AOR=8.23 95% CI (3.23-17.01)) more likely to use the system than the others. The association with system quality was two times (AOR=2.2 95% CI (1.34-3.09)) and with information quality was also aproximately two times (AOR=1.94 95% CI (1.12-3.23)).

Among the factors that affect service quality, 222 (72%) think that the IT support staff do not understand their needs, 191 (62%) believe that the initial training was not adequate and 227 (73%) were also unhappy with the frequent power interruption in the study hospitals.

Conclusion

The results of this study show that service quality has a strong correlation with user satisfaction, hence to IS success in low-resource settings. Therefore, system implementation efforts in those settings should focus on improving the service quality such as power infrastructure, IT support and trainings. Further study on the interrelationship between D&M constructs and HIS success in those settings is in progress.

Taming the Data Quality Dragon – A Theory and Method for Data Quality by Design

Jens H. Weber[a,b], Morgan Price[a,b], Iryna Davies[b]

[a] *Department of Computer Science, University of Victoria, Victoria, BC, Canada*
[b] *Department of Family Practice, University of British Columbia, Vancouver, BC, Canada*

Abstract

A lack of data quality (DQ) is often a significant inhibitor impeding the realization of cost and quality benefits expected from Clinical Information Systems (CIS). Attaining and sustaining DQ in CIS has been a multi-faceted and elusive goal. The current literature on DQ in health informatics mainly consists of empirical studies and practitioners' reports, but often lack a holistic approach to addressing DQ 'by design'. This paper seeks to present a general framework for clinical DQ, which blends foundational engineering theories with concepts and methods from health informatics. We define an architectural viewpoint for designing and reasoning about DQ. We introduce the notion of DQ Probes for monitoring and assuring DQ during system operation. The concepts presented have been validated in a real-world case study.

Keywords:
Information Management [L01.399]; Engineering [J01.293].

Introduction

The issue of clinical DQ has many facets. There is not yet a single commonly accepted standard definition of this concept; there however has been growing consensus on a number of aspects that have to be taken into account when discussing DQ in a health informatics context. Weiskopf and Weng have mapped DQ issues reported in the CIS literature to five quality attributes (*completeness*, *correctness*, *currency*, *plausibility* and *concordance*) [1]. The published literature on these DQ attributes is primarily of empirical nature or focuses on a particular practical aspect of defining, measuring or improving DQ for a particular purpose [2]. The lack of a fundamental theory and method for engineering CIS for DQ presents an impediment to the design and evolution of better health systems. The purpose of this paper is to define such a theory and method, referred to as *DQ by Design* (DQbD).

Methods

The DQbD method is based on the engineering paradigm of *functional decomposition*, in which complex system behaviour is broken down into more elementary discrete functions. We incorporated the idea of *Design by Contract (DbC)* from component-based software engineering and extended it to enable assertions over DQ concerns. We introduced and defined the concept of *DQ Probes* as a way to make DQ related assertions in pre- and post-conditions associated with CIS data processing functions. Our theory and method have been validated in several CIS data projects, including our project on building a third generation primary care CIS research network [3].

Results

We have formalized a taxonomy of five types of DQ probes:

Table 1 – Taxonomy of CIS Data Quality Concerns

	DQ Type		Clinical Example
0	Intrinsic	Conformance	Is diabetes on the problem list coded or uncoded?
1	Intrinsic-meta	Provenance	Recency of last A1c test in a diabetic
2	Extrinsic-internal	Internal concordance	Do patients on insulin have Diabetes on their problem list?
3	Extrinsic-external	External concordance, currency	Are the same allergies present in the hospital and primary care information systems? Which were updated most recently?
4	Statistical	Plausibility	Is the expected prevalence of diabetes in a practice (as determined in their EMR) for males 55-70 similar to published regional, jurisdictional, or national averages?

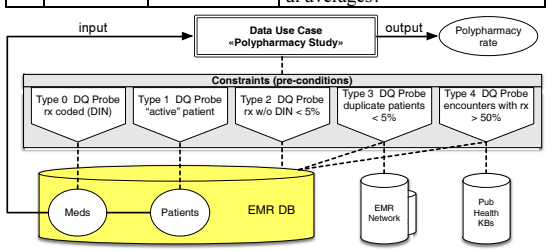

Figure 1 – DQ Probes in pre-conditions of Data Use Cases

We developed an architectural view point for designing CIS system use cases with explicit deployment of DQ probes. Our theory has been validated in a real-world project [3].

A Medical Image Backup Architecture Based on a NoSQL Database and Cloud Computing Services

Luan Henrique Santos Simões de Almeida[a], Marcelo Costa Oliveira[a]

[a] *Laboratório de Telemedicina e Informática Médica, Instituto de Computação, Universidade Federal de Alagoas, Maceió, AL, BR*

Abstract

The use of digital systems for storing medical images generates a huge volume of data. Digital images are commonly stored and managed on a Picture Archiving and Communication System (PACS), under the DICOM standard. However, PACS is limited because it is strongly dependent on the server's physical space. Alternatively, Cloud Computing arises as an extensive, low cost, and reconfigurable resource. However, medical images contain patient information that can not be made available in a public cloud. Therefore, a mechanism to anonymize these images is needed. This poster presents a solution for this issue by taking digital images from PACS, converting the information contained in each image file to a NoSQL database, and using cloud computing to store digital images.

Keywords:
Cloud Computing; NoSQL Database; PACS.

Introduction

The Picture Archiving and Communication System (PACS) is an approach widely used to store digital images. In 2010, Teng et al. [1] stated that in 2014 the United States produced approximately 100 Petabytes of medical images. Nevertheless, PACS is limited in current scenarios, with high investment in data centers and limited physical storage. Therefore, adopting a scalable environment that can persist data as long as needed and withstand varying loads is essential.

Cloud Computing is able to provide an elastic and appropriate environment for a set of applications besides providing hardware and software resources as a service, providing a low-cost storage with high reliability and security [2]. Thus, cloud computing becomes the ideal setting for several health applications, providing a great resource for storage and digital image processing. However, DICOM images contain private patient information; therefore, a mechanism to anonymize these images is necessary. The objective of this poster is to build an automated backup environment of anonymized medical images derived from PACS into a public cloud, powered by a NoSQL database.

Materials and Methods

The experiments were developed using the PACS solution from dcm4che project, the Amazon S3 public cloud and 1761 computed tomography (CT) images in the DICOM standard. The patient information contained in the DICOM file was stored in a MongoDB NoSQL database since these DICOM files are formed by tags that are similar to the key-value documents in MongoDB. As shown in Figure 1, the images are generated by acquisition modality equipments, sent to the PACS, read by the backup manager, and uploaded to the cloud after removing personal information.

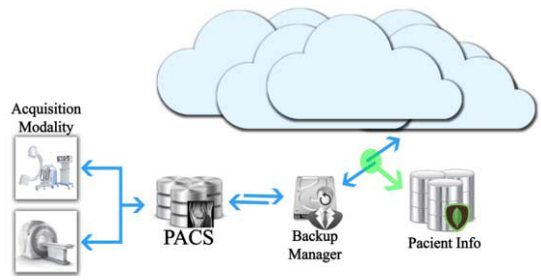

Figure 1 - Architecture overview

Results and Conclusion

The environment was built to be a fail-safe system by using MongoDB documents as log reports. Through these log reports, the environment will be able to recognize in which task the backup process stopped and continue from that point. The reverse way is also possible and is in development. In other words, the system will be able to identify the patient ID from the patient name, recover the file from the cloud, then place the patient information inside this file, and identify them. The query for patient information was optimized due to the use of MongoDB documents instead of regular SQL databases since it is possible to parallelize queries and these documents consisting of key-value pairs. Using a NoSQL database allows integration between other health bases within the big data concept in a near future.

Digital Imaging and Electronic Data Capture in Multi-Center Clinical Trials

Thomas M. Deserno[a], Verena Deserno[b], Daniel Haak[a], Klaus Kabino[a]

[a]*Department of Medical Informatics, Uniklinik RWTH Aachen, Germany*
[b]*Clinical Trial Center Aachen (CTC-A), Uniklinik RWTH Aachen, Germany*

Abstract

While medical image data is managed in picture archiving and communication systems (PACS) via the digital imaging and communications in medicine (DICOM) protocol, electronic data capture systems (EDCS) in clinical trials lack PACS interfacing. This complicates the trial workflow and increases errors, time, and costs. In this work, four system architectures of image integration for multi-center trials are analyzed with respect to data, function, visual, and context integration levels. We propose an open source-based architecture composed of OpenClinica, DCM4CHE, and Weasis for EDCS, PACS, and Viewer, respectively.

Keywords: Clinical Trials, Clinical Research, Imaging Biomarkers, Image-based Surrogates, Image Management System Integration, Workflow Integration

Introduction

Providing surrogate endpoints in clinical trials, medical imaging has become increasingly important in personalized medical research [1]. Electronic data capture systems (EDCS) are used to record research data while picture archiving and communication systems (PACS) manage subject's imaging data. Despite the digital imaging and communications in medicine (DICOM) protocol, EDCS and PACS are currently not interconnected. Particularly in multi-center trials, manual data interchange yields errors, delays, and additional costs.

Materials and Methods

The clincial PACS is separated from the research PACS, where all DICOM data is de-identified but linked to the subject matrix and electronic case report form (eCRF) in the EDCS. For storage, the research nurse might operate in either system as the leading component. For retrieval, DICOM objects might be viewed via stand-alone DICOM viewer or integratively via Web-based browsers (Figure 1).

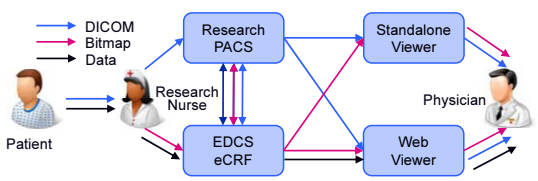

Figure 1

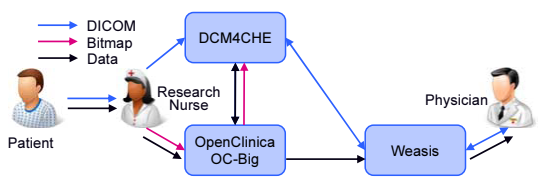
Using EDCS as primary system, there are four system architectures:

1. Image data are stored via EDCS as binary large object (BLOB). Retrieval may be supported via a Web-based DICOM viewer.
2. DICOM data are transferred via EDCS to the research PACS for storage, de-identification, and retrieval.
3. DICOM data are directly sent to the research PACS, and identifiers are handed back to EDCS' subject matrix.
4. Results from manual or automatical image analysis are stored in the PACS (e.g., DICOM Structured Reporting).

Results

For Level 1, EDCS and viewer have to support BLOB and DICOM data, respectively. Level 2 requires DICOM functionality in the EDCS, and both PACS and viewer have to support web access to DICOM persistent objects (WADO). To accept DICOM objects in the PACS directly, appropriate links to EDCS are required. For Level 4, the viewer component must support advanced DICOM services yielding full data, function, visual, and context integration.

We suggest OpenClinica, DCM4CHE, and Weasis as open source components for EDCS, PACS, and Web viewer.



Discussion & Conclusions

The successive levels of EDCS/PACS integration provide increasing functionality in mutli-center trials. At all levels, the EDCS is considered as primary system best supporting the research nurses' workflow. This is in contrast to van Herk, who tightly integrates the medical PACS as primary system, transferring the DICOM identifyiers into the eCRF [2].

An Exponential Increase in Regional Health Information Exchange With Collaborative Policies and Technologies

N. Lance Downing [a, b], Steven Lane [c], Mathew Eisenberg [b], Christopher Sharp [b], Jonathan Palma [a], Northern California HIE Working Group, Christopher Longhurst [a]

[a] Stanford Children's Health, [b] Stanford Health Care, [c] Sutter Health, Palo Alto Medical Foundation

Abstract

In the United States, the ability to securely exchange health information between organizations has been limited by technical interoperability, patient identity matching, and variable institutional policies. Here, we examine the regional experience in a national health information exchange network by examining clinical data sharing between eleven Northern California organizations using the same health information exchange (HIE) platform between 2013-2014. We identify key policies and technologies that have led to a dramatic increase in health information exchange.

Keywords:

Electronic Health Records; Health Information Exchange.

Introduction

As part of the Meaningful Use program, the U.S. government legislated incentives and penalties to encourage HIE, citing reasons of patient safety, potential cost savings, and patient engagement. Thus far, widespread adoption and benefits have been limited, though there have been promising results in reducing emergency department usage of redundant diagnostic testing and unnecessary hospital admissions. Here, we describe policy and technology changes associated with a dramatic increase in regional secure health information exchange across a national HIE network.

Methods

11 of the 12 health systems in Northern California that use the same electronic health record (EHR) and integrated HIE vendor (Epic Systems, Verona, WI) provided their regional HIE data. We examined the HIE activity between November, 2013– November, 2014 as measured by the number of clinical summaries received by each institution from the other 10 during this period. Additionally, we identified key policy and technology changes during this timeframe that may have contributed to the extraordinary increase in secure health information exchange.

Results

A steady increase in HIE volume is seen throughout this period with a marked increase in certain institutions at specific time points (Figure 1).

Discussion

We observed a dramatic increase in secure HIE during this period that coincides with changes in institutional policies and HIE functionality. Patient authorization requirement policies differ between these institutions, ranging from none, only if the patient has an encounter in a confidential department, or always at the point of care. During the 2014 period, most of the organizations adopted open HIE policies; waiving patient authorization requirement unless specifically restricted by the patient or clinical context.

Additionally, the institutional policies to automatically query regional organizations for patient matches varies, with options for permitting both sending and receiving queries. Changes to both the authorization requirement policy and auto-query functionality coincided with a dramatic increase in HIE volume.

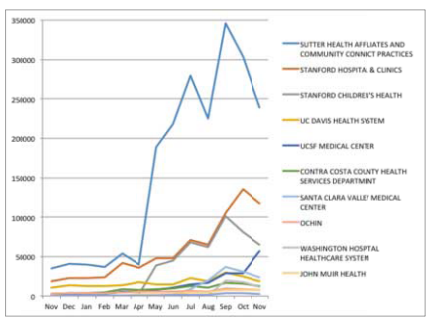

Figure 1 – Clinical Summaries Received by Organization

Conclusion

A striking increase in secure HIE is seen in this regional use of a single vendor HIE network due to changes in patient authorization policies and the use of new automated HIE functionality.

Towards Standardized Patient Data Exchange: Integrating a FHIR Based API for the Open Medical Record System

Suranga N. Kasthurirathne[a], Burke Mamlin[b,c], Grahame Grieve[d], Paul Biondich[b,c]

[a] School of Informatics and Computing, Indiana University – Purdue University, Indianapolis, IN, USA, [b] Indiana University School of Medicine, Indianapolis, IN, USA, [c] Regenstrief Institute Inc., Indianapolis, IN, USA, [d] Health Intersections Pty. Ltd. , AU

Abstract

Interoperability is essential to address limitations caused by the ad hoc implementation of clinical information systems and the distributed nature of modern medical care. The HL7 V2 and V3 standards have played a significant role in ensuring interoperability for healthcare. FHIR is a next generation standard created to address fundamental limitations in HL7 V2 and V3. FHIR is particularly relevant to OpenMRS, an Open Source Medical Record System widely used across emerging economies. FHIR has the potential to allow OpenMRS to move away from a bespoke, application specific API to a standards based API. We describe efforts to design and implement a FHIR based API for the OpenMRS platform. Lessons learned from this effort were used to define long term plans to transition from the legacy OpenMRS API to a FHIR based API that greatly reduces the learning curve for developers and helps enhance adhernce to standards.

Keywords:

HL7; FHIR; Interoperability; Standards; Electronic Medical Records.

Introduction

Healthcare quality is enabled by the accessibility and effective use of clinical data. The specialized nature of medicine and the ad hoc implementation of clinical information systems have led to the fragmentation of health information and medical care [1]. These limitations spurred efforts to effectively exchange patient data between various stakeholders across the enterprise, and led to the development of HL7 V2 and V3 standards. The FHIR standard is a next generation standard framework introduced in response to limitations in HL7 V2 and V3 [2]. FHIR has much to offer OpenMRS, a mature Open Source EMR system that is widely used across resource limited settings [3]. This paper describes efforts to design and develop FHIR support for OpenMRS. We demonstrate the feasibility and value of adopting FHIR for OpenMRS and develop an architectural plan to transition from the legacy OpenMRS API to a FHIR specific API.

Methods

We leveraged OpenMRS's modular architecture to develop an add-on module to provide a FHIR based API for OpenMRS. The FHIR module integrates the HAPI FHIR API for modeling and populating FHIR resources. The module exposes a FHIR API that could be accessed internally via API calls, or externally using FHIR specific user requests. The FHIR API receives user requests and serves them by calling the domain specific legacy OpenMRS API.

Results

We developed a production worthy FHIR module that could be used to fulfill basic user requirements for exchanging clinical data. The initial version of the module supports the import / export of OpenMRS clinical data in the form of FHIR standards for person, patient, location, observation, allergy intolerance, condition and encounter resources. The module is able to import / export FHIR resources in either xml or json. The module can also manage changing versions of OpenMRS domain objects via a strategy pattern that populates FHIR resources based on the underlying version of the OpenMRS platform. Each FHIR resource complies with the latest FHIR specification, which stood at Draft Specification for Trial Use (DSTU) 2 at time of submission.

Discussion

We perceive that the FHIR API will be widely adopted as it is based on a hugely popular standard, and removes the need for system developers to learn the OpenMRS domain model. However, we anticipate that implementer uptake will be a slow process that will happen gradually overtime. The FHIR module will initially be installed in parallel with the existing domain specific API. However, we propose a way forward to gradually retire the legacy OpenMRS API in favor of the standardized FHIR API. These efforts represent proper separation of concerns between EMR developers and champions of interoperability, and enables better interoperability across a wider range of healthcare IT infrastructure.

Development of Clinical Database System Specialized for Heavy Particle Therapy

Masami Mukai[a], Yutaka Ando[b], Yuki Yokooka[a], Yasuo Okuda[a], Masayoshi Seki[c], Masahiro Kimura[d], Hiroshi Tsuji[b], Tadashi Kamada[b]

[a] Medical Informatics Section, National Institute of Radiological Sciences (NIRS), Chiba, Japan
[b] Research Center for Charged Particle Therapy, NIRS, Chiba, Japan
[c] Global-for Co., Tokyo, Japan, [d] Fujitsu Systems East Limited, Saitama, Japan

Abstract

We have developed a data archiving system for study of charged particle therapy. We required a data-relation mechanism between electronic medical record system (EMR) and database system, because it needs to ensure the information consistency. This paper presents the investigation results of these techniques. The standards in the medical informatics field that we focus on are Integrating the Healthcare Enterprise (IHE) and 2) Health Level-7 (HL7) to archive the data. As a main cooperation function, we adapt 2 integration profiles of IHE as follows, 1) Patient Administration Management (PAM) Profile of IHE-ITI domain for patient demographic information reconciliation, 2) Enterprise Schedule Integration(ESI) profile of IHE-Radiation Oncology domain for order management between EMR and treatment management system(TMS). We also use HL7 Ver2.5 messages for exchanging the follow-up data and result of laboratory test. In the future, by implementation of this system cooperation, we will be able to ensure interoperability in the event of the EMR update.

Keywords:

Radiotherapy, Database, Strandards, IHE, HL7.

Introduction/Purpose

Our hospital has a mission of clinical research for radiotherapy. Charged particle therapy (carbon ion) was started in 1994, and over 9,500 cases have been treated by November, 2014. To accomplish this mission, we managed multi-system such as electronic medical record systems (EMR) and charged particle therapy treatment management system (TMS).

In 2000, we started to operate the Advanced Medical Information Database System (AMIDAS) for archiving the radiotherapy information. With the starting of EMR, we allocated a role to information systems as follows, EMR: input data related radiotherapy, AMIDAS: make report and summary of radiotherapy. So the AMIDAS is required to construct a mechanism to collect the data which is input by end-user on EMR.

Methods

The data targeted for the cooperation are following: (1) patient demographic information, (2) tumor related information, (3) radiation plan information, (4) follow-up information (tumor effect, advance reaction, mortality, etc.), (5) laboratory results, (6) treatment delivery information. We divided the implementation process into two stages and examined it as two steps: (1) investigated the availability of IHE [1]. (2) investigated the use of HL7 messages.

Results

This cooperation function was realized by two IHE integration profiles as follows, (1) Patient demographics and visit information: PAM Integration Profile, (2) Radiotherapy order and delivery information: ESI Integration Profile. For communication of treatment follow-up information and laboratory test we defined context and used HL7 messages.

Discussion

We show the comparison results using standard with original sysytem-interface in Table 1.

Table 1– The Comparison of Standard with original messages

Comparisonpoint	Standard-IHE	Standard-HL7	Orignal interface
Meeting number of times	little	few	much
The use of the library	possible	possible	impossible
Time to make specifications	short	middle	long

Conclusion

In comparison with original message system interface, it may be said that the system which was developed using a standardization technology has interoperability. From the standpoint of system-operation by using standards, when we will renew the EMR, AMIDAS can receive the data from EMR without software modification.

Interoperable Archetypes With a Three Folded Terminology Governance

Rune Pederson[a,b1], Gunnar Ellingsen [a,b]

[a] *University Hospital of North Norway, Tromsø, Norway*
[b] *Telemedicine and eHealth research group, Arctic University of Norway, Norway*

Abstract

The use of openEHR archetypes increases the interoperability of clinical terminology, and in doing so improves upon the availability of clinical terminology for both primary and secondary purposes. Where clinical terminology is employed in the EPR system, research reports conflictinga results for the use of structuring and standardization as measurements of success. In order to elucidate this concept, this paper focuses on the effort to establish a national repository for openEHR based archetypes in Norway where clinical terminology could be included with benefit for interoperability three folded.

Introduction

Initiatives using an openEHR architecture have been established for two primary purposes: (a) to build a national repository of common semantic data elements for collaborative EPR systems, and (b) to serve a large EPR vendor in building their system portfolio around the openEHR technology. The Clinical Knowledge Manager for archetypes in Norway is scheduled to contain between 1000 and 2000 archetypes, archiving information about how new archetypes are translated, modelled, and shared. This will give a common understanding of the clinical content of EPR systems over regional, national and global boundaries coordinated by the National Administration Office of Archetypes (NRUA). The increased focus on process-oriented systems across different health care organizations also presupposes standardization in the form of shared terminologies like NIC/NANDA, ICD, SNOMED-CT, and ICNP. This will generate an automatic and reliable use of terminology for sharing semantic interoperable information. By operating openEHR archetypes and terminology integration, it is possible to structure EPR content in a multilevel modelling approach that includes templates, archetypes, and a reference model. Within this structure, reuse of EPR data for research purposes and sharing information between heterogeneous practices become possible.

Results

Throughout the last three years, the use of OpenEHR archetypes has grown to gain a national anchorage in Norwegian healthcare. From the outset, a national collaborating group is coordinating with the vendor to build a national repository of OpenEHR archetypes. At the time it seems obvious that clinical terminologies are the connecting factor between the work with archetypes and the Norwegian Directorate of Health's focus on terminology work. With this as a backbone we observe that when clinical variables become structured and the semantic interoperability is governed by the possibilities within the OpenEHR platform, the sharing of information over local, national and global boundaries, for primary and secondary use of information, gain new possibilities.

Method

Qualitative methods (interpretive) have been applied, grounded in the first author's participation and contribution in the work accomplished. observations and description of ongoing work has been followed by interviews with members of the regional and national initiatives, which so far includes 9 interviews arround the archetype governance, several interviews and observations on the use of clinical terminology, and conversations with end users of the Clinical Knowledge Manager while guiding them to become users.

Discussion

Health authorities worldwide have faced a growing pressure to accomplish a smooth information flow among multi-organizational health systems. The motivation for this stems from the need for a streamlined work processes across organizational boundaries, and from the need to ensure quality of treatment and care of patients and secondary use purposes. To avoid mediating problems to reach primary and secondary target it becomes essential that standardized terminologies for different domains can be integrated to structured data elements in the EPR system. Although terminology standards are used on a daily basis in health care work, we know little about the processes of how these terminologies come into being and about how they are co-constructed with daily work.

Conclusion

Equal for both archetypes and terminology is that information used for any given purpose on a local or national level can be reused with another purpose both locally, nationally, and globally (the three levels). For archetypes that are a) approved in the national governance processes, b) increasing in number, or c) comprise clinical support repositories, there will be opportunity for terminology binding. An increasing number of archetypes, more than 1000, will in the end be accessible in an open repository. Further, each archetype that is translated or modelled will be compared or reviewed with the purpose of being added to the global repository.

Standardization of Information about Birth in the Obstetric Discharge Summary

Zilma S Nogueira Reis[a], Juliano S Gaspar[a], Isaias J R Oliveira[a], Andreia C de Souza[b], Thais A Maia[c]

[a] *Faculty of Medicine, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil*
[b] *Postgraduate Studies in Technology in Health, Pontificia Universidade Católica do Paraná, Maringá, Brazil*
[c] *Postgraduate Studies in Information Systems and Knowledge Management, Universidade FUMEC, Belo Horizonte, Brazil*

Abstract

Clinical information about the birth composes an important set of data to the documentation about the care provided during childbirth. Formalized in the document Obstetric Impatient Discharge Summary (OIDS), such information are essential for continuity of mother and child attention, in the health care network. The main paper's objective is to propose an Information Model for this document based on ISO Standard 13606 for interoperability between health information systems in Minas Gerais, Brazil.

Keywords:
Patient Discharge; Continuity of Patient Care; Health Information Systems.

Introduction

The OIDS is a strategic document able to collaborate in the construction of integration and interdependence between the hospital and primary care, using computerized communication channels. This study is a pilot that intends to prepare electronic systems of public information, already operational, for the challenges of transmission of clinical data.

Methods

This is a qualitative study with methodological exploratory purposes, which seeks to systematize and standardize the reference document model, aiming at interoperability between electronic information systems in Minas Gerais, Brazil. The set of clinical data about childbirth was proposed with the formalities and informational structure necessary to preserve the semantics of the data.

Results

Starting from a set of clinical data previously proposed by domain experts[1] and the archetypes published by Health Department of the State of Minas Gerais [2], the clinical data set was reviewed. In order to address many possibilities of obstetric hospitalization, the information model was divided into two sections: one about women's health, and other about the newborn. Based on archetypes of ISO Standard 13606, the knowledge model was formalized using the tool LinkEHR Platform[3]. All the documents related to the information model are available on the project website: http://site.medicina.ufmg.br/cins/apoio-a-pesquisa-22/projetos/.

Discussion

The harmonization of essential information defined by clinical experts with the existing on the web page that contains the archetypes published by the Health Department of Minas Gerais resulted in the reuse of two existing archetypes and the creation of ten new ones. However, no adaptation was necessary for terminology. SISMater® is a system used to collect obstetric and neonatal clinical data in a maternity of a public hospital and the data from it will be used to complete the proposed information model to send information to the basic health units systems for continuity of patient care.

Conclusion

It is considered that the study achieved its objective, since the information model for the OIDS based on the ISO Standard 13606 was created. It is expected that the document ensure semantic interoperability to facilitate communication on health care network for the continuity of patient care and its clinical safety. As the future study, it is suggested to apply the information model in different maternities.

Hospitalization Discharge Summary: Standardization of Information Model

Andréia Cristina de Souza[ab], Claudia Moro[a], Zilma S N Reis[b]

[a]*Graduate Studies in Technology in Health, Pontifical Catholic Univeristy of Paraná (PUCPR), Curitiba, Brazil*
[b] *Faculty of Medicine, Federal University Minas Gerais (UFMG), Belo Horizonte, Brazil*

Abstract

Brazil has a long tradition in the use of health information systems, however – until now – there is no consensus on the minimum data set from which to compose discharge summaries. This article describes the metdodology used by a group of experts – members of WG1 of ISOTC 215 Health Informatics Brazilian mirror committe – to define the information model of the discharge summary. This paper describes the current status of the standardization process and the first pilot tests with this infomation content.

Keywords:
Discharge Summary, Information Model; Continuity of Care; standardization.

Introduction

The hospital discharge summary is an essential document to support efficient and effective continuity of care, allowing for information to be shared [1]. Although Brazil has more than 20 years experience in using health information systems, so far there is no consensus on the minimum data set from which to compose the discharge summary. This article describes the methodology used by a group of experts – members of WG1 of the ISOTC 215 Health Informatics Brazilian mirror committee – to define an information model for discharge summaries.

Materials and Methods

Experts from government, academia, and private institutions – members of WG1: Frameworks, Architectures and Models, from the Brazilian mirror committee of ISO TC 215 Health Informatics – decided to work towards a proposal for a national information model for discharge summaries. A survey was then conducted to gather public and private hospital discharge summary examples around the country, as well as international guidelines (Australian, Canadian, and UK national standards, and ASTM – CCR), and reviews of national and international articles on the subject. [3].

Discharge summaries were collected from different regions of Brazil. One major contribution to the experts' work was a master's degree dissertation from the Catholic University of Paraná that identified the most relevant informational elements used in discharge summary, titled "Identification of the Contents of Standard Discharge Summaries."

Results

The final analysis resulted in a comprehensive discharge summary information model. The full information model is accessible at the WG1 site: http://gt1.medicina.ufmg.br/. The proposal of the discharge summary content was revised by WG1 members at ABNT (an ISO representative in Brazil) to be published for national public consultation in one month.

Conclusion

The forseen schedule entails public consultation ending in February 2015, and the document will be revised and published as a national standard in May 2015, at the latest.

This initiative will certainly contribute to the promotion of better continuity of care in Brazil.

Acknowledgment

The authors express their gratitude to the experts members of the WG1 of ABNT/CEE-78 and to FINEP.

The Challenge of e-Health Presence on a Petroleum Platform: Using Telemedicine to Make Operation of Pre-Salt Wells a Reality

R Nunes Ferreira[a], T Lopes da Rosa, C Benevenuto de Campos Lima[b], G Brito Alves de Lima[b], P dos Santos Ramos[c], T Dias da Silva, A Barbieri[a], E Takeo Ueda[a]

[a]Technological Research Institute, IPT, São Paulo, Brazil
[b]Federal Fluminense University, UFF, Niterói, Brazil
[c]Halliburton, Rio de Janeiro, Brazil

Abstract

Telemedicine can be defined as the use of electronic media for the transmission of clinical data and information from one location to another using information technology and telecommunication in order to provide immediate clinical health care at long distances. This new approach can involve specialized medical service centers in the oil production at great distances from the offshore installations in Brazil. The importance of the right health diagnosis, taken at the proper time, will make a serious difference in the facilities, which will be located around 300 km offshore. This paper presents an overview of telemedicine and its different applications, comparing them according to level of maturity and applicability. Important results from a case study in a fixed oil platform are analyzed. At the end of this work, the strategy of telemedicine implementation in a Brazilian petroleum operator is discussed.

Keywords:

MeSH; E-Health; Telemedicine

Introduction

With more than 352 square kilometers, Santos is the largest marine sedimentary basin in Brazil, going from the southern coast of Rio de Janeiro to Santa Catarina State. In this area, there are nine oil and gas production facilities and one gas onshore processing plant. There are two fixed production units and FPSOs (Floating Production Storage and Offloading) [12]. Located more than 300 km off the Brazilian coast, these production units can have more than 100 people on board each unit. In case of emergency situations they must have a specialized medical service. The long distances from land make it impossible to move people rapidly to a hospital, and decisions on the health of patients should be made in the shortest possible time. In this scenario, there is a need to have a structured telemedicine system and partnerships with specialized Brazilian hospitals [1].

Methods

The method proposed in this paper consists of the implementation of a telemedicine pilot project in an oil operator in Santos basin. One important factor to consider is the improvement of assistance to victims of accidents or illnesses on offshore platforms and areas without specialized medical service. The telemedicine system applied to an oil operator will be able to transmit images and sound between different terminals, enabling clinical examination at a distance [2].

Results

The results of the pilot project showed important medical achievements. It was possible to perform diagnosis from the hospital using medical information received from the platform. During the pilot period there were 124 calls in a period of 65 days, with an average of 1.9 visits per day, through connections with videoconferencing.The telemedicine pilot proved the technical feasibility, even using existing communication systems such as satellite networks and radio links. In the first pilot steps it was not clear who should call the hospital's medical specialists, the HSE team onboard or the doctor on duty onshore. The pilot results clarified this. It will be necessary to train all involved about the technologies of videoconferencing and new digital medical equipment.

Conclusion

There was consensus across the medical staff that the technology associated with a large hospital as a partner can support health services, even with an increase in the number of people on board and new production facilities, as is the situation at the studied company. Even with the existing infrastructure of communication it was possible to perform all the services demanded by the pilot, increasing the reliability of offshore diagnosis and improving support to onshore decisions.

Archetype Development Process of Electronic Health Record of Minas Gerais

Thais Abreu Maia[a], Cristiana Fernandes De Muylder[b], Rodrigo Mendonça Queiroga[c]

[a] *Project Manager at Health Department of Minas Gerais, Belo Horizonte, MG, Brazil*
[b] *Professor and researcher of Stricto Sensu Program of Administration and Information System and Knowledge Management, FUMEC University, Belo Horizonte, MG, Brazil*
[c] *Operations Manager at Vivver Systems Ltd., Belo Horizonte, MG, Brazil*

Abstract

The Electronic Health Record (EHR) supports health systems and aims to reduce fragmentation, which will enable continuity of patient care. The paper's main objective is to define the steps, roles and artifacts for an archetype development process (ADP) for the EHR at the Brazilian National Health System (SUS) in the State of Minas Gerais (MG). This study was conducted using qualitative analysis based upon an applied case. It had an exploratory purpose metodologically defined in four stages: literature review; descriptive comparison; proposition of an archetype development process and proof of concept. The proof of concept showed that the proposed ADP ensures the archetype quality and supports the semantic interoperability in SUS to improve clinical safety and the continuity of patient care.

Keywords:

Electronic Health Record; State Medicine; Archetype Development Process.

Introduction

The EHR is defined as one or more repositories integrated that supports continuity of patient care [1]. The health system of Minas Gerais State choose ISO Standard 13606 to develop it. The ADP is a type of knowledge management carried out by health professionals, which ensures consistency of archetypes used in the EHR [1] [2]. However, there is no literature about systematizing archetypes modelling [3]. Considering this scenario, what should be the steps, roles and artifacts for the archetypes development process used in EHR for SUS in MG?

Methods

This is a qualitative study which was divided into 4 stages: 1- literature review; 2- descriptive comparison; 3- archetype development process for SUS in MG and 4- proof of concept.

Results

Stage 1: identified the work of [1], [2], [3], [4] and [5].

Stage 2: systematized steps, roles and artifacts identified.

Stage 3: established ADP for EHR of SUS in MG that followed a process known as PDCA proposed by [2].

Stage 4: approved the model.

Discussion

The proposed ADP allows for control of the archetype development and especially the reduction of time to modeling it to according to SUS legislation. Additionally, the incorporation of management requirements to archetype quality requirements support the reduction of rework.

Conclusion

It is considered that the study met the objective. Study findings will enable increased data reliability for the secondary data use, allow better adaptation of the archetypes of science development speed in the health area and support the semantic interoperability in SUS to improve clinical safety, the continuity of patient care and archetype quality through its governance. Evaluation of necessity to determine time for each step is suggested as a future study.

Acknowledgments

Thanks for support to FAPEMIG, CNPq and CAPES.

Unanticipated consequences of hospital-based insulin management order sets

Eunme Cha, Sherita Hill Golden, Joseph Finkelstein

Johns Hopkins University School of Medicine, Baltimore, Maryland, USA

Abstract

Recent studies demonstrated risks to patient safety associated with implementation of electronic applications for medication management in ambulatory care. This study was aimed at demonstrating similar phenomenon in a hospital setting. After introduction of computerized order set targeting hypoglycemia, the frequency of hypoglycemia significantly decreased from 1/1/07 to 12/31/08. In contrast, the frequency of hyperglycemia increased at the same time from 1/1/07 to 12/31/07. Only after subsequent introduction of a hospital-wide standardized insulin order set including hyperglycemia policies frequency of hyperglycemic episodes declined. Hypo/hyperglycemia is associated with adverse clinical outcomes in the inpatient setting. Retroactive analysis showed that if hypoglycemic and hyperglycemic policies were introduced simultaneously, unexpected increase in frequency of hyperglycemic episodes could have been avoided. These data are informative in identifying unanticipated consequences of an insulin management order sets focused entirely on hypoglycemia. A balanced approach in implementing insulin management guidelines concurrently addressing both hypoglycemia and hyperglycemia policies is warranted.

Keywords:

order sets, patient safety, hypoglycemia, hyperglycemia, clinical guidelines

Introduction

In this study, we determined the monthly trend in glycemic control parameters from 1/1/07 to 12/31/08, using the hospital's glucometer database. Throughout 2006 and 2007, a Hypoglycemic Policy, a Diabetes Nursing Superuser Program, and a uniform computerized subcutaneous insulin order set were implemented at Johns Hopkins Hospital. In addition on January 1, 2008, the Hyperglycemia Policy became effective for management of hyperglycemia at our hospital. It included a Hyperglycemia Orderset that guided prescribers in ordering basal, nutritional, and correction insulin with an emphasis on ensuring that insulin deficient patients were to always receive basal insulin and that patients treated with insulin on admission were not to be managed with sliding scale insulin only. We hypothesized that there would be a downward trend in percentage of patients with hypoglycemic and hyperglycemic episodes.

Materials and Methods

Implementation of a hospital-wide Hypoglycemia Policy resulted in a significant reduction in hospital-wide hypoglycemia. However, prior to a complimentary Hyperglycemia Policy, the frequency of hyperglycemia unexpectedly increased. Although not statistically significant, there has been a trend of declining hyperglycemia frequency, particularly severe hyperglycemic episodes (glucose levels >=300 mg/dL), following the implementation of a hospital-wide Hyperglycemia Policy and uniform subcutaneous insulin order set.

Discussion

Our data suggested that simultaneous, as opposed to consecutive, implementation of hypo- and hyperglycemia management strategies may have a more favorable effect on inpatient hyperglycemia trends and overall quality of care. A major limitation of our analysis is that we were unable to distinguish individuals with diabetes from those without diabetes in our existing point of care testing glucose database. While we would assume that the majority of the patients receiving finger-stick glucose readings have diabetes, this may not be the case. In our future analyses, glucometric results have to be stratified by the presence versus absence of diabetes to account for potential confounders in our observed associations.

Conclusion

Introduction of a hospital-wide glucose management program had a significant impact on reducing the frequency of hospital-wide hypoglycemia. Implementation of in-hospital insulin management guidelines may be optimized by introduction of a balanced approach addressing both hypo- and hyperglycemia simultaneously.

The Impact of Implementing a New Computerized Physician Order Entry (CPOE) System on Pharmaceutical Interventions in a Tertiary Brazilian Hospital

Vladimir Ribeiro Pinto Pizzo[a], Paula Brito Gonçalves[b], Lívia Maria Goncalves Barbosa[c], Debora Cecilia Mantovani Faustino de Carvalho[c], Margareth Ortiz de Camargo[d], Carlos Onofre de Lira[e]

[a] *Adult Intensive Care Unit, Hospital Sírio Libanês, Brazil*
[b] *Informatics Technology Division, Hospital Sírio Libanês, Brazil*
[c] *Pharmacy Division, Hospital Sírio Libanês, Brazil*
[d] *CIO, Hospital Sírio Libanês, Brazil*
[e] *Hospital Director, Hospital Sírio Libanês, Brazil*

Abstract

We analyzed trends in pharmaceutical interventions during the implementation of a new computerized physician order entry (CPOE) process in a tertiary hospital in Brazil. The new process utilized an eletronic interface that was designed in-house and an automatic order extension program. The new process reduced the number of order transcriptions and mitigated other potential CPOE-related errors [1].

Keywords:

Computerized Provider Order Entry, Medication error, Intervention.

Introduction

The beginning of our eletronic health system (EHS) implementation process was characterized by interface-related difficulties [2], Due to this, our organization maintained a setting for paper-based order entry with transcriptions and a 24/7 pharmaceutical evaluation for non-staff physicians. When we developed a more intuitive local solution associated with an automatic copy of the order entry ("copy robot") it was possible for physicians to place orders electronically. The aim of this poster is to show the trend of pharmaceutical interventions during this proccess.

Methods

We chose three reasons for order adjustment as study variables: "system problems," "adequacy of pharmaceutical form," and "duplication." These reasons for adjustment were indicated during routine pharmaceutical evaluation of orders. The data were evaluated for two periods–six months before and after June 2014–when the "copy robot" and CPOE systems were activated. The data were plotted in Microsoft Excel and statistically analyzed using an ANOVA single factor test. P values less than 0.05 were considered statistically significant.

Results

The number of prescriptions that needed an intervention decreased during the time periods studied ($p < 0.001$). There was no statistically significant difference in the number of pharmaceutical interventions for "system problems," an increased number for "adequacy of pharmaceutical form" ($p < 0.001$), and a decreased number for "duplication" ($p < 0.001$). Figure 1 shows these results. Light grey columns correspond to "adequacy of pharmaceutical form," dark grey to "duplications," and black to "system problems."

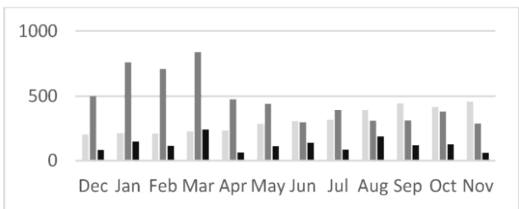

Figure 1 - Pharmaceutical Interventions Over Time

Discussion

Our strategy reduced the number of order transcriptions and minimized some errors like order "duplications." An increase in adjustments for "adequacy of pharmaceutical form" is considered a less dangerous pattern for our population.

Conclusion

The implementation models for electronic health systems should be adapted for each setting and place. Planning and continuous evaluation are key factors for success.

Methodology to Establish Associations between Data and Clinical Assessment for Computerized Nursing Process in Intensive Care Units

Daniela Couto Carvalho Barra[a], Grace Teresinha Marcon Dal Sasso[a], Fernanda Paese[a]

[a]Nursing Departament, Federal University of Santa Catarina, Brazil.

Abstract

Combining the Information and Communication Technologies (ICT) in the Nursing Process (NP) is a way to support their development in health contexts. The alliance between ICT and the NP integrates and organizes a logical structure of data and clinical information supporting nurses in decision-making. This manuscript describes the methodology used to articulate data and information cynical of Computerized Nursing Process (CNP), according to ICNP® 2.0, associating detailed clinical assessment of each human system to their diagnoses, interventions, and patient outcomes. This is a methodological study and technological production conducted in 2010, and is developed in three stages. It was possible to restructure the CNP from the associations between the data and clinical information of all human systems (cardiovascular, neurological, respiratory, renal, gastrointestinal, cutaneous, musculoskeletal, female / male and biopsychosocial) to their diagnoses, interventions, and results of Nursing.

Keywords:

Nursing informatics; Nursing Process; Terminology; Classification; Intensive Care Unit

Introduction

The Nursing Process (NP) is a care technology that guides the sequence of clinical reasoning and improves the quality of care. Combining the Information and Communication Technologies (ICT) in the NP is the way to support their development in health contexts. The alliance between the ICT and the NP promotes the quality and safety of care because it integrates and organizes a logical structure of data and clinical information supporting nurses in decision-making[1,2] .

The aim of this manuscript is to describe the methodology used for the articulation of data and clinical information of Computerized Nursing Process (CNP) according to ICNP® 2.0 associating detailed clinical assessment of each human system to their diagnoses, interventions and patient outcomes.

Materials and Methods

Methodological and technological production study conducted in 2010 by seven participants, a teacher and six post-graduate course students.

The association of data and clinical information was developed in three steps[2]:

1. Discussion and understanding of the standard International Organization for Standard 18.104. This standard includes the reference terminology model for diagnoses and nursing actions, thus making the standard a tool that facilitates the mapping of various terminologies and promoting the integration of information systems and electronic medical records.
2. Theoretical study on the International Classification for Nursing Practice (ICNP®) 2.0.
3. Combination of data and clinical information to diagnoses, interventions and outcomes of nursing. The base of knowledge was organized according to ICNP® 2.0.

The study was approved by the Ethics of the Federal University of Santa Catarina Committee (protocol 947/10).

Results

It was possible to restructure the CNP from the association between the data and clinical information of all human systems (cardiovascular, neurological, respiratory, renal, gastrointestinal, cutaneous, musculoskeletal, female / male and biopsychosocial) to their diagnoses, interventions and results of Nursing.

The ICNP® version 2.0 reflects major reformulations, as pointed out by nurses, and provides a technology rating system more robust and affordable for these professionals working in Intensive Care Units.

Conclusion

The method adopted from the three steps allows realization of the associations between data and clinical information, diagnoses, interventions, and outcomes of nursing, provides documentation on clinical practice, and support for ICU nurses' decision-making. The ICNP® is used as a basis of knowledge that facilitates organized thinking and clinical judgment for nurses.

Nursing Software for Emergency Triage (NSET)

Mandirola Brieux H. F.[abcd], Guillen S. [b], La Rosa F. [c], Moreno C. [c], Benitez S. [d]

[a] *Belgrano Hospital in San Martín, Buenos Aires, Argentina*
[b] *BIOCOM, Buenos Aires, Argentina*
[c] *HL7 Argentina, Buenos Aires, Argentina*
[d] *Hospital Italiano, Buenos Aires, Argentina*

Abstract

Determining the priority of attention in an Emergency Room (ER) has always been a difficult issue. Priority is determined with a simple triage system as people arrive at the hospital. It is important to establish how long they can wait for treatment. In order to obtain the best assessment of patients' conditions, we built a Nursing Software for Emergency Triage (NSET). The objective of this work was to assess the efficacy of the NSET versus the triage process without any software (TWS). Results showed that the NSET we built was a substantial help. With this software, we decreased significantly:1) the length of the triage system process, 2) the waiting time of patients in the waiting room, 3) the number of complaints and 4) the number of patients who walk away. In conclusion, the NSET improves and helps to define more accurately a patient's risk. NSET helps in the emergency department triage.

Keywords:

EMR; HL7;TRIAGE; Nurse; Computer; System; eHealth; MTS-Manchester; Medical Informatics; ER.

Introduction

In the Emergency Room (ER) staff do not attend to patients on a first come, first served basis; but according to the severity of the patient's condition. In an ER, we *must* know who needs help more urgently in the waiting room. Patients presenting themselves in the ER currently face unacceptable delays in initial treatment, and long, costly hospital stays due to suboptimal initial triage and site-of-care decisions. For the purpose of this work, the Manchester Triage System (MTS) was used to build a Nursing Software for Emergency Triage (NSET) to be used by triage nurses. Our hypothesis is that the NSET is better than a triage system without software (TWS) to categorize patients at the ER. [1,2]

Materials and Methods

Belgrano Hospital is located in the surrounding area of Buenos Aires city, Argentina, South America. It is a medium-level acute hospital. There are 200 beds, 8 critical care unit beds and 250 physicians. This study is a prospective study. The period of data collection for this work was from April 30th, 2014 to November 1st, 2014. In this period, we collected 1800 patients' data in the ER of the Belgrano Hospital, Buenos Aires, Argentina. During the data collection period we included patients who were treated in the ER. Twenty eight patients in total were excluded from the sample because some of their data were missing. The final sample included 1772 patients. Fifteen of them belonged to the NEST group and thirteen to the control group.

Results

The results were as follows: The triage time in the control group was 3.7 and in the NSET group 2.5 with a p less than 0,001. For the Left-without-being-seen index, the results for the control group were 4. 76 and for the NSET group 3. 98. The difference between the two samples was not significant waiting time of patients in the ER waiting room. In this case, there was a huge difference between both samples; the control group with an average time of 97 minutes against the NSET group with just 28 minutes. In the Complaint-index, the difference between the two groups was significant with the control group at 42.01 and the NSET at 14.62.

Discussion

Results showed that the NSET was of significant help and was better than the TWS. NSET allowed solving several problems and resulted in a better organization, whereas TWS did not.

Conclusion

Treatment priority in the ER may be subject to variation due to different levels of patient illness. We must give more importance to determining the risk for each patient in the moment they enter in the ER which is why triage is critical. The NSET improves and helps to assess more accurately the condition of a patient.

Abstract

Information is a key feature that health professionals need to exercise their profession with efficiency and quality. This study aims to present the experience of the usage of an electronic system for clinical documentation in nursing in a university hospital. It is a methodological research of technology production. The system was developed in four phases: Conception, Elaboration, Construction, and Transition, and was named Electronic Documentation System of the University of São Paulo Nursing Process (PROCEnf-USP™). The knowledge base of PROCEnf-USP™ was organized in hierarchy of domains and classes, according to NNN linkages.

Keywords:

Nursing Information Systems; Information Systems; Nursing Diagnoses; Classification System; Nursing Process.

Introduction

Health records are the primary information tool to improve clinical communication and evidence based practice. Structured documentation produces data that generate more meaningful and reliable information than free documentation [1]. Classification systems are instruments to improve the reliability, validity and usability of the nursing documentation [2]. The implementation of the NNN linkages (classifications of nursing diagnoses, outcomes and interventions) [2] in electronic nursing documentation system encourages nurses to adopt the nursing process, proves the diagnostic accuracy and the scope of the results obtained from the patients**.** The objective of this study is to present the experience of the usage of an electronic system for clinical documentation in nursing in a university hospital.

Methods

In this methodological research four cyclical phases of creation and assessment of technological product were used to develop the system, based on project management model in the Project Management Institute (PMI) [3]. Phases: Conceptualization - project scope was approved and defined. Estimated resources, problems and expected benefits were identified. Elaboration: problem domain was analyzed in order to complement the survey documentation of the use cases and modeling of system data. Construction: system development (prototype), aiming to refine the requirements, build and test their components. Transition: dissemination of the new system for the whole nursing team, user training, and evaluation of user satisfaction [3].

Results

The system developed is Electronic Documentation System of the University of São Paulo Nursing Process (PROCEnf-USP™). It allows clinical documentation, generates reports of the nursing process and provides decision support about diagnoses, expected results and nursing interventions [3]. This support system for clinical decision has both professional and academic environments, and it has been used since 2009 [1].

Conclusion

This project was funded by Brazilian government agencies for research support. PROCEnf-USP™ generates data for scientific research regarding the evaluation, accuracy and usability of the system.

A Trial of Nursing Cost Accounting using Nursing Practice Data on a Hospital Information System

Akiko Miyahira[ab], Kazuko Tada[ab] Masatoshi Ishima[ab], Hidenori Nagao[a], Tadashi Miyamoto[a], Yoshiaki Nakagawa[c], Tadamasa Takemura[b]

[a] *Hyogo Prefectural Amagasaki Hospital, Amagasaki, Japan*

[c] *Shikoku Medical Center for Children and Adults, Zentsuji, Japan*

Abstract

Hospital administration is very important and many hospitals carry out activity-based costing under comprehensive medicine. However, nursing cost is unclear, because nursing practice is expanding both quantitatively and qualitatively and it is difficult to grasp all nursing practices, and nursing cost is calculated in many cases comprehensively. On the other hand, a nursing information system (NIS) is implemented in many hospitals in Japan and we are beginning to get nursing practical data. In this paper, we propose a nursing cost accounting model and we simulate a cost by nursing contribution using NIS data.

Keywords:
Nursing Cost Accouting; Hospital Administration; Nursing Information System.

Introduction

In many cases, the results of nursing cost accounting are unrealistic for nursing staffs. Part of reason that it is difficult to adapt to activity-based costing is because it is hard to figure out realistic nursing activities [1]. A nursing information system (NIS) includes nursing practical data. So we consider that we are able to make a new nursing cost accounting model using these data.

Methods

Nursing cost accounting model

We are able to categorize nursing practices into three tasks: (a) variable tasks to patients, (b) fixed tasks to patients, and (c) other fixed tasks.

1. Variable tasks to patients include individualized care for each patient. For example, tasks such as toilet support, bed bath, and so on.

2. Fixed tasks to patients include basic infomaiton collection, orientation of administration, and so on. These tasks are performed regardless of patient.

3. Other fixed tasks are education, operating report, and so on. All nurses have the job of administration in the ward.

These tasks have some indicators of working. They are hours, payment, skill levels and so on. Therefore we can calculate costs about these indicators.

Data Extraction from NIS

Hyogo Prefectural Amagasaki Hospital has implemented a full EMR system. The EMR system has full NIS and the NIS has nursing practical data for each patient. Hyogo Prefectural Amagasaki Hospital has 192 categories of nursing practice and NIS has all nursing practical data of these categories.

Results and Discussions

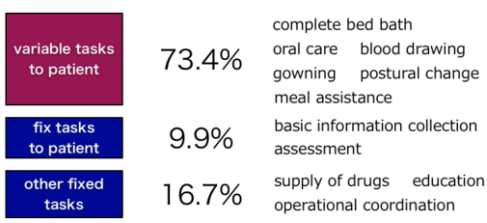

Figure1 – The ratio of three tasks

We could simulate the amount of nursing practices in the ward. For example, we analyzed variable tasks to patient by Diagnosis Procedure Combination (Japanese DRG) and we could predict nursing tasks and nursing costs.

An Electronic Nursing Patient Care Plan Helps in Clinical Decision Support

Wong CM[a], Wu SY[a], Ting WH[b], Ho KH[b], Tong LH[a], Cheung NT[a,b]

[a] *Health Informatics Section, Hospital Authority, Hong Kong SAR*
[b] *Information Technology Division, Hospital Authority, Hong Kong SAR*

Abstract

Information technology can help to improve health care delivery. The utilisation of informatics principle enhances the quality of nursing practices through improved communication, documentation and efficiency. The Nursing Profession constitutes 34% of the total workforce in the Hong Kong Hospital Authority (HA) and includes 21,000 nurses in 2012. To enhance the quality of care and patient safety in both hospitals and community care setting, it is essential that an integrated electronic decision support system for nurses is designed to track documentation and support care or service including observations, decisions, actions and outcomes throughout the care process at each point-of-care. The Patient Care Plan project was set up to achieve these objectives. The Project adheres to strict documentation information architecture to ensure data sharing is freely available. Preliminary results showed very promising improvement in clinical care.

Keywords:

Patient Care Plan; Efficiency; Documentation.

Introduction

The Patient Care Plan Project (PCP) is a new nursing function in the HA Clinical Management System (CMS) that depicts the identified care needs, treatment goals and the progress towards meeting the goals. Clear communication and appropriate assessment form the basis of providing vital and essential information for nursing interventions and initiating patient care plan in daily operation.

Methods

The HA information architecture was developed in 2002 to support a fast, robust and standardised electronic patient record (ePR) from data captured from various CMS function modules. The Generic Clinical Documentation (GCD) engine would manage the lifecycle of various information architecture elements such that the semantics of these elements (regardless of their source, whether internal or external) are preserved from design, creation, capture, use, reuse, and analysis. Forms created using this process and architecture will be semantic interoperable in different service modules. The PCP is constructed using this architecture.

The PCP is designed to indicate and identifies high risk patients based on assessments to provide early notifications to medical officers, nurses and allied health professionals. Validation rules and auto-calculation were utilised to assist and support decisions. System alert and logic are built-in and documented to track ongoing assessments, actions and responses to the high risk indicators. Risk prevention outcomes and standards from the current Nursing Standards for Patient Care in HA have been hard-coded in the system.

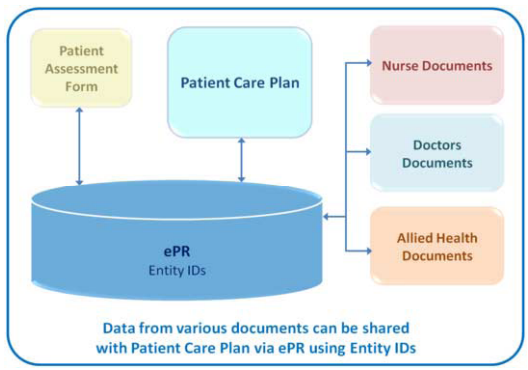

Figure 1 - Data sharing to support patient care plan

The project is governed by the Patient Care Plan Working Group under the Clinical Informatics Program Steering Group. An overview of the PCP has been included in the summary page and the care plan will be shared in the ePR for future development. Agreement for complete data sharing by members in the nursing systems starting from admission to hospitalisation and discharge with follow-up in outpatient department and community setting will achieve the requirements of standardisation of entities and terms (figure 1).

Results

The PCP helps to alert HA healthcare professionals to implement relevant, appropriate and specific interventions for high-risk patients. Decisions are based on professional knowledge supported by a comprehensive and coherent assessment which is freely available in the electronic medical record system. This co-ordinated flow of structured data and care planning processes are essential to all stakeholders in the patient's journey to maximise benefits for the patient.

Conclusion

The information architecture of the PCP excels itself in a clinically meaningful way; not only it enables data sharing from admission to discharge, data can be reused across different CMS function modules, and alerts HA healthcare professionals to response to high risk patients in risk reduction and prevention. There is pronounced added value in the Patient Care when end users are prompted to offer timely and appropriate care support to patients.

Clinical Decision Support to Implement CYP2D6 Drug-Gene Interaction

Pedro J. Caraballo, Mark Parkulo, David Blair, Michelle Elliott, Cloann Schultz, Joseph Sutton, Padma Rao, Jamie Bruflat, Robert Bleimeyer, John Crooks, Donald Gabrielson, Wayne Nicholson, Carolyn Rohrer Vitek, Kelly Wix, Suzette J. Bielinski, Jyotishman Pathak, Iftikhar Kullo

Mayo Clinic, Rochester, Minnesota, USA

Abstract

The level of CYP2D6 metabolic activity can be predicted by pharmacogenomic testing, and concomitant use of clinical decision support has the potential to prevent adverse effects from those drugs metabolized by this enzyme. Our initial findings after implementation of clinical decision support alerts integrated in the electronic health records suggest high feasibility, but also identify important challenges.

Keywords:

Clinical Decision Support Systems; Pharmacogenomics; Cytochrome P-450 CYP2D6; Electronic Health Records.

Introduction

Codeine and tramadol are opioid prodrugs commonly used in clinical practice to treat moderate pain. They have been associated with several adverse effects including respiratory depression and death. They are metabolized in the liver by the cytochrome P450 2D6 enzyme and transformed to their active metabolites which are responsible for their therapeutic effects. CYP2D6 enzyme is encoded by the *CYP2D6* gene and the enzyme activity varies among individuals but this variation can be predicted by pharmacogenomic (PGx) testing. In the case of codeine, high activity of CYP2D6 produces high levels of morphine and increases the risk of adverse effects. On the other hand, low activity produces low levels of morphine resulting in less pain control.

We present our initial findings after the implementation of PGx clinical decision support (CDS) rules integrated in the electronic health records (EHR) to alert on actionable polymorphism of *CYP2D6* gene to optimize dosing and prevent adverse effects from codeine and tramadol.

Methods

We developed a series of CDS rules to alert providers based on the results of PGx testing for *CYP2D6* and the documentation of the genotypes and phenotypes in the EHR. There were approximately 640 different genotype variations that were matched to eight phenotypes based on the level of enzyme activity: high metabolic activity (ultrarapid, extensive to ultrarapid, intermediate to ultrarapid), relatively normal activity (extensive, intermediate to extensive, intermediate) and low activity (poor to intermediate, poor). The CDS rules displayed alerts only for high or low activity. The CDS rules assessed all new *CYP2D6* genotype test results, matched them to one of the eight phenotypes, and documented the select phenotype as a problem in the problem list. Other rules assessed all codeine/tramadol orders and reviewed the problem list and PGx results. If there was an actionable result, the rule displayed a CPOE (Computerized Physician Order Entry) screen rule. The system also detected unreadable results and sent an email to the implementation team to initiate a manual review and documentation. All the alerts had a clear message indicating the clinical impact of the specific drug-gene interaction. They also had links to additional PGx education and treatment alternatives.

Results

Between 10/27/2013 and 7/31/2014 a total of 206 events were triggered by the CPOE screen rule and 45 (21.8%) of them were unreadable. The main cause of unreadable result was lack of discrete values on the PGx reports. The other 161 events displayed alerts due to increased activity (121, 75%) or decreased activity (40, 25%), see Table 1. The number of events was higher than the number of patients and providers, indicating that the same alert displayed multiple times for the same drug/patient/provider interaction.

Table 1 – CDS Events Based on CYP2D6 Phenotypes

Phenotypes	Events (n)	Patients (n, female %)	Providers (n)
Ultrarapid	49	18, 67%	27
Extensive to ultrarapid	72	24, 46%	39
Intermediate to ultrarapid	0	0	0
Poor to intermediate	15	12, 42%	14
Poor	25	13, 69%	17
Unreadable	45		

Conclusion

Implementation of CDS integrated in the EHR to selectively prevent CYP2D6 related drug-gene interactions is feasible, but encounters significant challenges. The PGx Lab reports are still evolving and they are in need of additional standardization to support stable electronic data integration with the EHR and to facilitate execution of CDS interventions. Provider understanding of drug-gene alerts and immediate response to the alerts requires additional analysis, seeking to prevent unnecessary and repetitive alerts.

A Scalable Architecture for Rule Engine Based Clinical Decision Support Systems

Soumi Chattopadhyay[1], Ansuman Banerjee[1], Nilanjan Banerjee[2]

[1]Indian Statistical Institute, Kolkata, India
[2]IBM Research, India

Abstract

Clinical Decision Support systems (CDSS) have reached a fair level of sophistication and have emerged as the popular system of choice for their aid in clinical decision making. These decision support systems are based on rule engines navigate through a repertoire of clinical rules and multitudes of facts to assist a clinical expert to decide on the set of actuations in response to a medical situation. In this paper, we present the design of a scalable architecture for a rule engine based clinical decision system.

Keywords:

Clinical decision support, Rule engine

Introduction

The core component of CDSS [1] consists of a rule inferencing system where characteristics of an individual patient are matched to a clinical knowledge base, and then patient-specific assessments or recommendations are presented to the clinician(s) and/or the patient for a decision. Commercial rule engines such as Drools [2] and ILOG [3] have shown to satisfy most needs of a CDSS. An evaluation of the performance of ILOG showed that the overall performance was generally satisfactory for small rule sets. However, hundreds of rule sets are possible in a real-time surveillence system and rule engines do not perform very well on large rule sets. In this paper, we propose an efficient and scalable framework for a rule engine based CDSS.

The Proposed Framework

The key idea behind the framework is a cache-based lazy loading mechanism that consists of rule clustering and hashing kernel, coupled with a prediction based technique for rule evaluation and faster actuation. The main motivation for rule clustering is to save the memory requirement for rule loading and to expedite rule firing by the rule prediction strategy. If we can efficiently and accurately predict the set of rules that are expected to be evaluated to truth based on the arriving facts, we can improve the rule firing time by triggering the actuations beforehand. The rule clustering step is done during preprocessing, whereas prediction is done at runtime. In the clustering step, two rules that have a common fact variable in their antecedents are put in the same cluster. The clusters are mutually disjoint. This ensures that only the rules in one cluster are affected by a fact and only that cluster gets loaded into production memory based on the matching facts at once. The prediction mechanism at run time only stores the last evaluation outcome of a rule in history. In this work, we experiment with two different prediction schemes: a deterministic scheme, in which a rule R is predicted to be true if it was true in the previous session, and a probabilistic scheme, in which the prediction is done with a certain probability.

Experimental Results

We implemented the framework with *JRuleEngine* [4] and evaluated its performance with a dataset of 16 rules defined over 32 fact variables. The rule base contains 5 clusters. Performance evaluation experiments were done using randomly generated sets of facts. Table 1 shows the memory gain (in %), the amount of memory saved using lazy loading of rules and used more intelligently for larger rule bases, with lazy loading of rules.

Table 1. No. of facts vs memory gain (in %)

Cardinality of Facts	*1*	*5*	*10*	*15*	*30*
Memory Gain(%)	*87.5*	*18.75*	*5.56*	*3.94*	*1.125*

Figure 1 shows the actuation time required in normal mode of operation, i.e., without prediction and with different prediction algorithms discussed above, against the number of facts. Our prediction based approaches for rule evaluation gains consistently over the normal mode of operation.

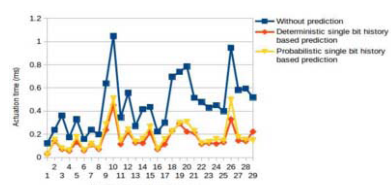

Figure 1. Number of facts vs actuation time

Conclusion

Despite all the benefits of rule engine based CDSS, they suffer from some performance bottlenecks. We propose a framework for improving the overall performance of the rule engine in terms of memory utilization and execution time. Experimental results show promising performance gain that can be leveraged for large-scale operations. In future, we plan to take up the evaluation of our proposed architecture for industry grade performance benchmarks.

Clinical Decision Support Based on Integrated Patient Models: A Vision

Kerstin Denecke[a]

[a] *Innovation Center Computer Assisted Surgery, University of Leipzig, Germany*

Abstract

Clinical decision making is non-trivial given the amounts of data and knowledge that needs to be considered. So far, medical knowledge, biological knowledge and patient data are separated from each other and need to be integrated mentally by a physician to form an overarching patient model. In this paper, we describe a vision for future decision support systems that link knowledge about organ functions, biological processes, treatment decisions and clinical data represented in repsective models. Requirements and challenges for realizing this vision will be collected.

Keywords:

Clinical decision support system; Digital patient model; Medical informatics applications; Health information system.

Introduction

The challenges we face nowadays in clinical settings, are that clinical data is distributed in several systems and available in multiple formats. Best practices and information about treatment plans and options are captured in biomedical literature or clinical practice guidelines. Not only the access to this data during diagnosis and treatment is a challenge, also its manual or automatic integration, analysis and interpretation. To address these problems, we consider the concept of model-based decision support. A digital patient model integrates various information entities that need to be considered within therapy planning and clinical decision making. It further describes relations between clinical parameters and sociological factors related to a specific clinical pathology. The medical knowledge can be modelled in different ways, and reflects different aspects, e.g. as functional, geometric or probabilistic graphical model. Our vision of model-based decision support is to integrate these different models in a clinical decision support system. Such integration will lead to an evidence- and model-based decision making. It is still unclear, how to integrate these models. In this work, we will describe the general idea and collect the requirements as well as challenges to be addressed for realising the vision.

Methods

Our concept of model-based decision support foresees three types of models: (1) A **decision model or predictive model** (e.g. realized as probabilistic graph) encompasses the medical knowledge on the diagnostic of the disease, the therapy decision including the therapy options, their risks for the patient and their relations to single information items relevant in decision making. (2) A **geometric or functional model** models an organ or organ function, and (3) A **patient specific data model** includes and integrates the relevant patient data (labor tests, examination results, medical report, signal and image data) in a standardized format.

Results

In order to realize a three layer model-based decision support technologies in three main areas are necessary: (1) Modelling of processes, diseases and clinical decision making, (2) Methods for linking data and models, (3) Ontologies and classification systems for describing the concepts of the models and providing the relations for inferencing. From the requirements result the following challenges:

- Modelling the decision processes in form of a digital patient information model is still time-consuming. To ensure a high quality of the models, human interaction is necessary in the modelling process. The challenge is to find the right balance between automatic model generation through data and text mining (at least for probabilistic graphical models) and manual generation. Geometric modelling requires segmentation which can be partially done automatically so far. The challenge is to improve automatic segmentation.
- Collecting all relevant patient data from the multiple information systems (situation description) is difficult due to vendor-lock and a broad landscape of information systems in use.
- Linking data semantically requires corresponding methods for data linking and semantic annotations.
- Missing common data models and use of different vocabularies complicate the integration of domain theory (model) and situation description (real patient data).

Conclusions

The main benefit of the presented approach is that functionalities of current information or clinical decision support systems are extended by:

- bridging the gap between system biological models and patient and clinical data (patient model) as well as medical knowledge data (decision model) – in order to make justified, well-grounded therapeutic decisions, and by
- improving semantic annotation and linking of the heterogeneous data – in order to support users with an integrated view on patient data and on knowledge about disease development and treatment.

Impact of Specific Alerts in Potassium-Increasing Drug-Drug Interactions

Emmanuel Eschmann, Patrick E. Beeler, Jürg Blaser

Research Centre for Medical Informatics, University Hospital, Zurich, Switzerland

Abstract

Alerts in potassium(K^+)-increasing drug-drug interactions (DDIs) are often ignored due to their low specificity. Although different approaches have been implemented to address DDIs, subsequent clinical studies revealed poor adherence to such alerts. We therefore suggest a novel alert concept currently being evaluated in a randomized clinical trial in a large teaching hospital. Highly specific reminders (to monitor K^+) and alerts (of hyperkalaemia) are displayed to the physicians of the intervention group, whereas reminders and alerts are suppressed in the control group. Preliminary analysis shows a high alert specificity. Furthermore, the physicians of the intervention group reacted significantly faster to a problematic situation arising during a K^+-increasing DDI compared to the physicians of the control group, indicating that this concept has an impact on physician behaviour.

Keywords

Decision Support Systems, Clinical; Drug Interactions; Hyperkalaemia; Randomized Controlled Trial

Introduction

Alerts in the context of potassium(K^+)-increasing drug-drug interactions (DDIs) are often ignored due to their low specificity, thus inducing alert fatigue. Approaches addressing this issue include (a) displaying relevant laboratory data in alerts, (b) suppressing less significant alerts by taking into account patient data, (c) removing alerts when the initiating conditions are no longer met, and (d) focussing on high-priority DDIs.

However, the clinical studies examining the impact of these approaches showed poor adherence to DDI alerts. Therefore, we combined these approaches, determined the optimal thresholds by analysing patient data, and are now evaluating the impact of this novel alert concept in a clinical trial.

Methods

A 12-month cluster randomized trial including all inpatients of a large teaching hospital (37,000 inpatients per year) was started in January 2014. Fourteen clinics were randomized to the intervention group and 15 to the control group. ICU stays were excluded. Both, at onset and during a K^+-increasing DDI, the physicians of the intervention group were (a) reminded to monitor K^+, if the current serum K^+ is unknown and no K^+ level measurement has been ordered, (b) warned against hyperkalaemia risk (when serum K^+ ≥4.9mEq/l), and (c) alerted of hyperkalaemia (when serum K^+ ≥5.5mEq/l). All reminders and alerts were non-interruptive, displayed in the electronic health records of the intervention group only, and were removed when the triggering conditions were no longer met. The adherence of physicians to reminders and alerts was reflected by the time elapsed between the reminder or alert activation and its deactivation due to a modification of the K^+-increasing DDI or ordering of a new serum K^+ measurement.

The Mann-Whitney-Wilcoxon test was used for statistics. A *p*-value of ≤0.05 was considered to be statistically significant.

Results

We analysed 1,964 alerts and reminders triggered in the first 10 months of the trial (1,262 displayed in the intervention group, 702 suppressed in the control group). On average 32.2 potentially severe K^+-increasing DDIs occurred per day in the intervention group. However, the physicians of the intervention group were only exposed to 2.8 reminders for K^+ monitoring, 1.1 warnings against increased hyperkalaemia risk, and 0.2 alerts of hyperkalaemia per day.

The physicians of the intervention group reacted significantly faster to an inadequate K^+ monitoring and to an elevated serum K^+ level compared to the physicians of the control group (Table 1).

Table 1 – Reaction time following reminders and alerts

Alert / Reminder	Reason for termination	Intervention group[a]	Control group[a,b]	p
K^+ monitoring reminder	K^+ monitoring	11.2 h	18.0 h	0.04
Alert of elevated K^+ or hyperkalaemia	K^+ monitoring	8.0 h	16.0 h	0.01
	K^+ increasing DDI stopped	4.0 h	6.0 h	0.05

[a] median; [b] alert / reminder displayed, but not logged

Conclusion

This preliminary analysis of our ongoing cluster randomized trial underlines the high specificity of the implemented concept (4.1 reminders and alerts compared to 32.2 K^+-increasing DDIs per day). Moreover, reaction time following reminders and alerts were shorter in the intervention group compared to the control group, i.e. physicians of the intervention group reacted significantly faster to a problem arising during a K^+-increasing DDI compared to the physicians of the control group. Therefore, this novel alert concept has an impact on physician behaviour and may increase patient safety.

The clinical outcome parameters will be analysed after the completion of the study in January 2015 to be presented at MEDINFO2015.

Detecting, Monitoring, and Reporting Possible Adverse Drug Events Using an Arden-Syntax-based Rule Engine

Karsten Fehre[a], Manuela Plössnig[b], Jochen Schuler[c], Christina Hofer-Dückelmann[d], Andrea Rappelsberger[e], Klaus-Peter Adlassnig[a,e,*]

[e] *Section for Medical Expert and Knowledge-Based Systems, CeMSIIS, Medical University of Vienna, Vienna, Austria*

Abstract

The detection of adverse drug events (ADEs) is an important aspect of improving patient safety. The iMedication system employs predefined triggers associated with significant events in a patient's clinical data to automatically detect possible ADEs. We defined four clinically relevant conditions: hyperkalemia, hyponatremia, renal failure, and over-anticoagulation. These are some of the most relevant ADEs in internal medical and geriatric wards. For each patient, ADE risk scores for all four situations are calculated, compared against a threshold, and judged to be monitored, or reported. A ward-based cockpit view summarizes the results.

Keywords:

Adverse drug events;Arden Syntax rule engine;clinical decision support;drug monitoring; pharmacovigilance.

Introduction

The increasing use of medical drugs has raised the risk of drug-related damage, especially in elderly patients. Although a legal obligation to report adverse drug events (ADEs) has been instituted in several countries, the number of reported cases remains low. Only about 10–20% of medication errors and 1–13% of detected ADEs are reported. ADE detection and reporting is a time-consuming and expensive task. Hospitals need an efficient way to quantify the numbers and severity of ADEs before corrective action can be taken by pharmacists and physicians.

Methods

An ADE cockpit for detecting, monitoring, and reporting possible ADEs has been developed in the iMedication project [1]. The core of the software implementation is a decision support system employing a hybrid approach, combining the IHI Global Trigger Tool method and Morimoto's classification to detect suspected ADEs. The system's knowledge base consists of medical logic modules which encode medical expert knowledge in Arden Syntax [2], and the modules are executed by an Arden Syntax rule engine on a server. The data to be processed are derived from various sources—the hospital information system, an electronic health record, and entered information—and divided into six categories: demographic data, laboratory test results, the patient's symptoms, diagnoses, medications, and hospital events. The aggregated information of a single patient is delivered to the Arden Syntax server, which returns a detailed interpretative summary for each identified ADE consisting of a) an ADE risk score which reflects the degree and severity of the ADE, b) the institutions to be informed, depending on the severity of the ADE, c) the triggers having fired, and d) the complete patient information used for interpretation.

Results

Four clinically relevant situations (hyperkalemia, hyponatremia, renal failure, and over-anticoagulation) were selected as exemplary conditions. The corresponding knowledge bases containing the respective ADE triggers together with their significance, expressed as scores between 1 and 3, were established in close collaboration between experienced clinicians and medical knowledge engineers. All four possible ADEs were analyzed for 100 patients. The test yielded a sensitivity of 88% (3 false negatives out of 25) and a specificity of 87.7% (46 false positives out of 375).

Conclusion

The proposed system is suitable for: (a) quality assurance by retrospective evaluation of clinical data in regard of suspected ADEs, (b) active feedback for clinicians during patient treatment, and (c) pharmacovigilance reporting.

Systems Medicine for Multiple Myeloma: A Review on Decision Support Systems

Matthias Ganzinger, Christian Haux, Christian Karmen, Thomas Wetter, Petra Knaup

Heidelberg University, Institute of Medical Biometry and Informatics, Heidelberg, Germany

Abstract

Systems medicine is a current approach trying to improve treatment for patients with complex diseases by analyzing as much phenotype and genotype data as possible for the disease in question. For individualized treatment decisions in clinical practice, this task has to be supported by an application system with decision support component. For a research project on systems medicine we reviewed methods for decision support. Criteria for selecting a method are derived from characteristics of the data and the diseases. They include, among others: dimensionality of data and existence of a priori models for diseases. As a result we decided to implement a prototype system with a case-based reasoning component for systems medicine on multiple myeloma.

Keywords:
Systems Medicine, Clinical Decision Support Systems, Multiple Myeloma, Case-based Reasoning

Introduction

For complex diseases like cancer, it is known that frequently only a fraction of patients will benefit from a treatment and some will experience more side effects than others. Factors causing response to therapy or side effects are hardly known.

In systems medicine, these problems are addressed by using as many data sources as possible for the treatment decision. This does not only include data on an individual patient, but also data on other patients suffering from the same disease. Data types include genotype data, as they are measured by microarrays and next-generation sequencing, as well as phenotype data. However, to draw clinically relevant conclusions from such a huge amount of data, support through information technology (IT) is inevitable. A decision support component is a key element of an IT system for systems medicine.

Currently, we have built an IT system for the systems medicine research project: "Clinically-applicable, omics-based assessment of survival, side effects, and targets in multiple myeloma" (CLIOMMICS). As part of this work we reviewed decision support methods for applicability in systems medicine.

Methods

We analyzed literature on rule-based and experience-based methods for decision support systems; especially with respect to our reference disease *multiple myeloma*. Criteria for this assessment included the capability of the approach to handle:

- high dimensional data, especially genomic data
- lack of comprehensive formal *a priori* knowledge like genomic pathways about multiple myeloma
- uncertainty in source data

Based on these factors we selected a decision support method for our prototype implementation.

Results

Rule-based approaches such as rules engines and deductive classifiers are based on the availability of a formal representation of knowledge such as an ontology. Decisions are inferred by analyzing relations modelled into the knowledge base. In contrast, approaches like machine learning or case-based reasoning (CBR) are based on prior experiences made in treatment of the disease. In such an approach, no prior formal representation of knowledge is necessary.

For multiple myeloma, we currently do not have a comprehensive model of the disease available. Thus, we decided to implement the IT system for CLIOMMICS with a CBR decision support system. Publications suggest that CBR is applicable to genomic data despite their high dimensionality [1–3].

Currently, a prototype decision support system based on CBR has been developed for CLIOMMICS. A case basis of about 3000 patients with clinical and genomic data is available.

Discussion

A major challenge in this approach is the adequate definition of similarity functions reflecting the heterogeneous character of the parameter set. Especially in genomic data, significant noise is expected. In the future we may investigate a hybrid system combining CBR and a rule-based approach to add medical knowledge from sources like medical guidelines.

Conclusion

CBR seems to be a promising approach to implement decision support for systems medicine.

Bridging the Gap between Clinical Practice Guidelines and Archetype-Based Electronic Health Records: A Novel Model Proposal

Diego Garcia[a], Claudia Maria C. Moro[a], Lilian Mie M. Cintho[a]

[a] *Graduate Program in Health Technology, Pontifical Catholic University of Paraná, Curitiba, Brazil*

Abstract

The lack of a unique, standardized format for representing data and knowledge is one of the existing difficulties to integrating decision support into Electronic Health Records (EHRs). Objective: Propose an archetype-based model to allow the integration of Clinical Practice Guidelines (CPG) and EHRs; design and implement this proposed model. Results: A generic model was designed for the integration of CPG into EHRs, and an archetype-based EHR for Chronic Kidney Disease Prevention based on rules from CPGs, was made as a proof of concept of this novel integration.

Keywords:

Archetypes; Clinical Practice Guideline; Electronic Health Records.

Introduction

Archetypes and SNOMED-CT terminology have been used to integrate Electronic Health Record (EHR) and Clinical Decision Support Systems (CDSS), typically to represent information [1]. Although archetype architectures have been used in CDSS development [2], until now, no work has presented or described a model integrated with an EHR. Based on this, the goal of this study is to propose a model of an archetype-based EHR that allows this integration, and is implemented using the Clinical Practice Guideline (CPG) for Chronic Kidney Disease (CKD) prevention.

Methods

To integrate CPGs into an EHR using archetypes it is necessary that the system handles archetypes, rules and EHR data. To provide low coupling between components and system, we used independent services for each one of these three types of resources. To collect data based on archetypes structure we used an EHR with a component that automatically generates forms from archetype. To provide decision support, it was necessary to incorporate an inference engine for the developed EHR.

The implementation of the proposed model was carried out as a proof of concept to demonstrate the applicability of the model.

Results

The main result of this work is the implementation of the information level of the archetype dual-level architecture of the proposed model. It consisted of seven components for handling archetypes, rules and EHR data: three repositories, three services and the forms generator. The components were implemented using Java technology and a PostgreSQL Database Management System (DBMS). Representational State Transfer (REST) architectural style was used to implement the services. Also, openEHR Java Reference Implementation (RI), provided by openEHR Foundation, and GDL libraries were used to parse archetypes and rules content. The EHR was implemented as a Java Server Faces (JSF) application containing a component to automatically generate forms to collect data based on archetypes definitions. It was necessary to implement the openEHR specification using standards required by the JSF Application. JBoss Drools Expert was used as inference engine to provide decision support capabilities.

The validation of the components was conducted using existing archetypes to validate the archetype, EHR data repository and service, and the forms generator. It used openEHR and ISO/EN 13606 archetypes. All openEHR archetypes were successfully processed and forms were generated. However, the forms generator was unable to process ISO/EN 13606 archetypes as the main class of clinical archetypes (Entry) as they are more generic in this model. To validate the execution of the rules, data based on archetypes structure were collected and the EHR detected the rules contained in the rules repository that were applicable to them. The rules were executed and the resulting data were in compliance with the CPG.

Conclusion

This study presented a model of an archetype-based EHR with CPG integration that bridges the gap between these systems. The EHR was able to provide decision support based on rules and data structured in archetypes, demonstrating the feasibility and applicability of the proposed model. Along with the proposed model, the implementation of the components is also one of the contributions of this study as there are few works reporting this step, particularly the component that automatically generates forms from archetypes, which is a problem that hinders the implementation of archetype-based EHR.

Virtual Oncological Networks – IT Support for an Evidence-based, Oncological Health Care Management

Katja Heiden[a], Monika Sinha[b], Britta Böckmann[b]

[a] *adesso AG, Dortmund, Germany*
[b] *Department of Medical Informatics, University of Applied Sciences and Arts, Dortmund, Germany*

Abstract

An interdisciplinary and intersectoral coordinated therapy management along Clinical Practice Guidelines can ensure that all patients receive adequate diagnostic, treatment, and supportive services that lead most likely to optimal outcomes. Within the research project "Virtual Oncological Networks", guideline-compliant pathways are defined and enacted within a Health Care Management Platform to support treatment planning and ongoing care of oncological diseases.

Keywords:

Clinical Practice Guidelines; Quality Assurance; Oncological Networks; Health Care Management.

Introduction

Cancer treatment is a collaborative effort and requires an effective co-ordination of all health activities and professionals[1]. The implementation of a cross-institutional health care management can enhance process and outcome indicators, particularly for breast cancer patients[2]. This can be realized by developing pathways based on existing Clinical Practice Guidelines (CPGs). As part of the research project, integrated care processes for breast, colon, and prostate carcinoma are defined and enacted within a Health Care Management Platform (HCMP).

Materials and Methods

The definition of standardized care processes based on existing CPGs is done by the help of *PathGuide*[3]. In a step-by-step approach relevant CPG recommendations are annotated, formalized and used for process modeling. The guideline-compliant pathways are represented within a Health Level (HL7) version 3 model. For enactment and visualization these processes are integrated into the HCMP to enable providers of regional oncological care coordinating all aspects of a patient's physical and psychosocial needs.

Results

Each guideline-compliant process is described by a set of medical, supportive and administrative activities. In addition, collaboration across professions are specified to ensure well-coordinated processes. For enactment, the HL7 models are parsed and visualized within the HCMP. Each process is linked to treatment objectives to determine the patient group, who can be treated by this process (e.g. recurrence-free survival or analgesia). This allows the definition of different treatment options, which can be used based on the type of cancer and the patients' health conditions to individualize therapy. For example, the treatment objective recurrence-free survival for a breast cancer treatment call for a breast-conserving therapy, mastectomy or chemotherapy, while the treatment objective analgesia requires a palliative care. The whole approach is clarified in Figure 1. Next, results are evaluated with a network of oncology experts.

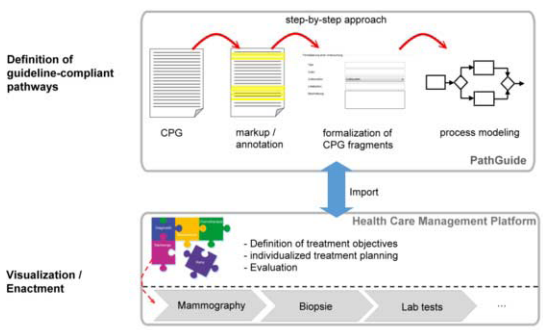

Figure 1 – Evidence-based Health Care Management

Conclusion

The use of CPGs can ensure the co-ordination of care across different professions and sectors. The definition of guideline-compliant processes allows an individualized treatment planning and can effect a continuous quality improvement of oncological care.

Computer-Interpretable Clinical Guidelines: A Review and Analysis of Evaluation Criteria for Authoring Methods

Soudabeh Khodambashi[a], Laura Slaughter[b], Øystein Nytrø[a]

[a] *Department of Computer and Information Science, Norwegian University of Science and Technology, Norway*
[b] *Oslo University Hospital, Oslo, Norway*

Abstract

There are a variety of authoring tools and methods for producing computer-interpretable clinical guideline (CIG). This work is a review of the evaluation of tools and methods currently in use to author CIGs. The aim of this paper is to present the results of a literature review on the evaluation criteria. Both controlled database search and a subsequent snowballing were used to identify relevant literature. The evaluation criteria and evaluation methods of CIG-related themes were manually identified in the found literature. Based on the 32 relevant papers found, 68 evaluation criteria were identified which were then classified into ten themes. We identified the most and least frequently mentioned areas of concern in evaluation which indicate areas that have been neglected in system evaluation.

Keywords:

Computer-interpretable clinical guidelines; Evaluation criteria.

Introduction

A multitude of tools and methods have been developed to support authoring of computer-interpretable clinical guidelines (CIGs) [1]. The tools that are designed for encoding guidelines have been evaluated in numerous studies [2]. The criteria they have chosen in their evaluation methodologies are based on these authors' desire to ensure effective implementation and to assess the impact of the tools. This paper reviews the themes, criteria found in a selection of reported research on CIG. The review covers evaluation studies as well as comparative studies. The scope of this paper is limited to research describing modelling languages and the modelling/encoding process. Papers related to application of CIGs, systems for executing CIGs or clinician's compliance with recommendations are out of the scope.

Methods

Our research method was literature review in the Journal of Biomedical Informatics, Journal of the American Medical Informatics Associations, Methods of Information in Medicine, International Journal of Medical Informatics, Artificial Intelligence in Medicine and Digital Bibliographic Library Browser. A total number of 131 papers were included based on title and abstract. In a second phase, other related papers for review were selected based on snowballing method to the identified articles in addition to the searches in the databases.

Results

From the 32 fully reviewed papers, we identified a total of 68 evaluation criteria. We identified similar evaluated criteria and grouped them in order to generate the evaluation themes covered in research studies. The evaluation themes were subdivided into 10 main categories: knowledge extraction performance, tool functionality, modelling perspective, user's effect on modelling, didactic support, usability, guideline verification and validation, integration, maintenance features and comparative analysis on encoding process.

Discussion

The themes receiving most attention based on the results and the numbers of identified criteria were tool functionality and evaluation on modelling perspective. At the other end, the themes given least attention were knowledge extraction performance, verification and validation, and maintenance features. The limited number of studies in the domain of usability indicates the least concern in the evaluation of the tools and methods in the literature. Based on the number of proposed tools and methods in the domain of CIG, we expected to find more articles on usability testing of the tools.

Conclusion

Overall the results of this review shows that the field of CIG is still mainly concerned with technical and functional aspects of the technology and has yet to move to a stronger focus on its users. A comprehensive overview of appropriate evaluation methods and criteria which consider different aspects is necessary to facilitate further work in the field. The results motivate the development of a comprehensive evaluation framework covering more aspects of tool and method properties and qualities.

Acknowledgments

I am grateful for the support of the EviCare project (http://www.evicare.no), Norwegian Research Council grant no 193022, contributing project partners and Eric Monteiro.

Internal domain-specific language based on Arden Syntax and FHIR

Eizen Kimura[a], Ken Ishihara[a]

[a] *Dept. Medical Informatics of Medical School of Ehime University, Japan*

Abstract

We demonstrate the concept of Arden Syntax, which is like Domain Specific Language (DSL), for describing decision support rules that take advantage of modern programming language concepts. Using object relational mapper and meta programming enables the conceptualization of FHIR resources from various data sources, and reduces the complexity of knowledge retrieval in decision rules.

Keywords:

CDSS, Arden Syntax, FHIR, DSL, ESB, DWH

Introduction

The HL7 International Arden Syntax (AS) for Medical Logic Modules (MLMs) [1] was developed to standardize the representation of medical knowledge for clinical decision support. However, the widespread adoption of AS has been a problem because of two issues. First, it is difficult to supply skilled developers because AS is an external domain-specific language (DSL), thereby limiting learning opportunities. Second, there is no standardization of data access methods in AS, and every healthcare entity has to implement specific queries for their data source. There is no unified method to manage bulk messages from a variety of data sources, such as the enterprise service bus (ESB) or data warehouse (DWH). This has become known as the curly braces problem. These issues decrease the portability of clinical decision rules. In this study, we developed a novel scheme to overcome these issues.

Methods

We used Ruby meta programming to implement internal DSL [2] that closely conformed to the AS specification. Mapping between DWH and Fast Healthcare Interoperability Resources (FHIR was developed with Ruby on Rails (RoR) to absorb various database structures (Fig. 1). HL7 messages exchanged between systems were converted into FHIR objects through ESB. To manipulate medical knowledge from DSL, we extended the FHIR object so that it was able to transparently query against DWH to retrieve historical medical records.

Results

We were able to translate the clinical decision support rule written in AS into our developed DSL with equivalence and expressivity. We avoided using custom SQL queries against the specific schema of the database, and retrieved information using a standardized concept and query method. HL7 messages, as transaction data and historical medical records, were unified into FHIR objects, so we were able to describe a rule for inquires about events from past to present, and from every data source in a unified way. This significantly reduced the amount of data query code and made simple rules.

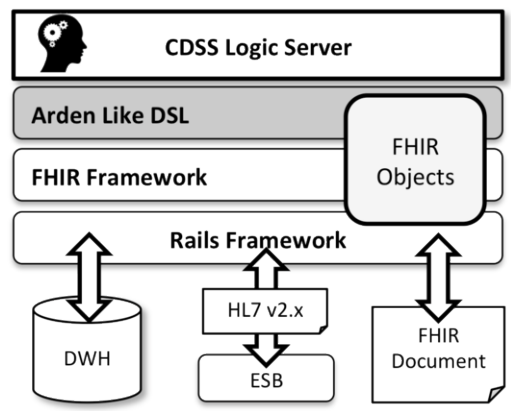

Figure 1. CDSS DSL framework with FHIR Objects

Discussion

Compared to a pure AS DSL, our approach has the advantage of availability of a modern development environment; for example, test-driven development may contribute to building solid rules representing complex clinical guidelines. And we can take advantage of the many developers, and entry-level work for implementing clinical decision rules may be reduced.

Computationally Comparing and Analyzing All Published Scoring Systems for Diagnosis of Disseminated Intravascular Coagulation

Fabrício S. P. Kury, M.D., James J. Cimino, MD

National Library of Medicine, US National Institutes of Health, Bethesda, Maryland, USA

Abstract

The clinical literature presents four different scoring systems (SS) for the diagnosis of disseminated intravascular coagulation (DIC) by four institutions: ISTH, JMHLW, JAAM and KSTH. In this study a Java program was written to retrieve medical records from the MIMIC-II database and apply the criteria of all four. The program then quantified the agreement of each DIC SS with each other and demonstrated notorious dissent. Furthermore, the average internal composition of each score was also quantified. All source code produced is available for download at https://github.com/fabkury/hedicim.

Keywords:

Disseminated intravascular coagulation; EHR databases; MIMIC-II; Clinical Decision Support Systems

Introduction and Methods

Disseminated intravascular coagulation is a **c**ondition with reported mortalities above 40% [1] for which four different organizations have published diagnostic criteria (scoring systems – SS): the International Society of Thrombosis and Hemostasis (ISTH), the Japanese Ministry of Health, Labour and Welfare (JMHLW), the Japanese Association for Acute Medicine (JAAM), and the Korean Society of Thrombosis and Hemostasis (KSTH) [1]. All patient data required by these SS are available in structured form in the MIMIC-II database, permitting a computer program to readily apply the clinical logic and establish diagnosis of DIC.

A Java program was written to retrieve, from MIMIC-II, hospital admissions of non-neonates containing an ICD-9 code of a condition known to predispose the patient to DIC [2]; read all needed patient data; then apply each DIC SS, thereby identifying the moments of start and end of diagnosis as per each DIC SS. The program calculated the periods of time and cases of agreement between the DIC SS, and, additionally, reported the average proportion that each individual criteria inside each DIC SS represented towards their final scores.

Results and Discussion

A total of 36 different data elements were found to be needed from MIMIC-II. From 8284 hospital admissions of non-neonates found eligible, 1584 cases were identified with at least one DIC SS affirming a diagnosis earlier than 12 hours before patient death. Table 1 demonstrates how much each SS agreed with each other. The conclusion from our study is a great disagreement among seemingly similar clinical diagnostic criteria. In accordance with the previous literature, the JAAM SS was found to be the most sensitive, and the ISTH SS the most specific. Moreover, only 171 (10,8%) of the hospital admissions with any DIC diagnosis had been ICD-9-coded for DIC (code 286.6). The average internal composition of the scores is presented in the poster, which also demonstrates some encountered caveats to the conversion of a paper guideline into a computer, and exposes some difficulties which we faced that are inherent to retrospective analyses of EHR databases. This study exemplifies the enabling power of structured data for clinical decision support systems, because our computerized analyses would be much less feasible if the DIC scoring systems were not mostly based on data that are commonly available in structured form in EHRs.

Precedent Approach to Decision Making in Clinical Processes

Malykh Vladimir L.[a], Guliev Yadulla I.[a]

[a] *The Medical Informatics Research Center, Ailamazyan Program Systems Institute of RAS, Russia*

Abstract

This poster describes the results of promising research in the field of clinical processes management and decision making support. The authors formulated common scientific problems connected with the modelling of treatment processes. The research is supported by grants from the Ministry of Education and Science of the Russian Federation (the project RFMEFI60714X0089).

Keywords:

Medical information system; Model of clinical processes; Decision-making system in medicine.

Introduction

For a long time, the attempts to use mathematical methods in medicine, in particular for solving the problems of establishing the right diagnosis, forecasting the development and the outcome of clinical processes, preventing any critical situations, making decisions and managing clinical processes in general, lead to partial results that only had practical meaning in limited contexts of a particular nosology. Multiple difficulties connected with construction of the clinical process for a particular nosology, as well as the difficulty of identification of parameters for such models, did not allow for a wide adoption of clinical process models in MIS. It may look like the model approach would prevail but there is another approach to the same problems which may come forward, namely the precedent approach, and there are sufficient grounds to take it into consideration.

Methods

A recognized and experienced Russian specialist in the field of data processing methods N.G. Zagoruyko recognizes that there are two common application-oriented approaches for building systems for decision making support based either on precedents or on models. Both approaches are considered of equal worth, and both have their advantages and shortcomings. In the model approach, “just as is the case about any generalization, some features of the system behavior are lost at each particular point of decision space. When decision is based on precedent, as our experience shows, local specifics are taken into account, which allows for more correct decisions (N.G. Zagoruyko).

Results

Malyh et al. [1] offer precedent approach for building a model of clinical processes of the class of controlled stochastic processes with memory. The model is based on two postulates: modeling in the class of stochastic processes and the precedential effect of decision-making in medicine. The conceptual basis of the model has a clear, meaningful interpretation for medical professionals.

Conclusion

As a conclusion, we present a plan of tasks to be addressed in order to implement this large project aiming at decision making support in clinical processes: (1) Development of a model that could be used as a standard theory of the knowledge system and diagnostic and treatment process. (2) Development of methodology for formalization and normalization of clinical facts ensuring fast changes of the evaluation system and terminologies, and standardization of language describing facts. (3) Development of a scaled architecture of the clinical data bank that could be used in separate medical facilities and nationwide as a national standard. (4) Development of methods for relevant search of clinical precedents. (5) Development of methods ensuring the relevance and integrity of the clinical data bank for long periods of time. (6) Development of software tools for decision making support based on the precedent approach.

Semantic Interoperability in Clinical Decision Support Systems: A Systematic Review

Luis Marco-Ruiz[a,b], Johan Gustav Bellika[a,b]

[a] *Norwegian Centre for Integrated Care and Telemedicine, University Hospital of North Norway*
[b] *Department of Clinical Medicine, Faculty of Health Sciences, University of Tromsø*

Abstract

The interoperability of Clinical Decision Support (CDS) systems with other health information systems has become one of the main limitations to their broad adoption. Semantic interoperability must be granted in order to share CDS modules across different health information systems. Currently, numerous standards for different purposes are available to enable the interoperability of CDS systems. We performed a literature review to identify and provide an overview of the available standards that enable CDS interoperability in the areas of clinical information, decision logic, terminology, and web service interfaces.

Keywords:

Clinical Decision Support Systems; Semantic Interoperability; Terminologies; Clinical Models; Ontologies.

Introduction

The interoperability and reuse of Clinical Decision Support (CDS) systems with other health information systems has become one of the main limitations to their broad adoption[1–3]. Definition of the standards for EHR interoperability, decision logic, and terminologies has represented a step towards CDS systems' reuse. For the CDS systems to be reusable across organizational boundaries a high degree of semantic interoperability (SiOp) is needed. We aim to provide an overview of the main types of standards covered in the literature, facilitating a clearer picture of the available standards to the CDS community for building interoperable systems.

Methods

We searched PubMed, IEEE Xplore, and ScienceDirect for the SiOp approaches in CDS. . Inclusion criteria were: (a) Study describing a CDS with SiOp capabilities with other systems; (b) paper covering mechanisms for the CDS reuse by means of its information, knowledge, or logic representation.

Results

We includeed 26 papers in the review available in [4]. 23% (n=6) covered the application of medical decission logic and guidelines representation formalisms; 62% (n=16) presented the use of clinical information standards; 38% (n=10) made use of semantic web technologies such as ontologies; 42% (n=11) covered the use of standard terminologies; and 19% (n=5) proposed the use of web services for CDS encapsulation or new techniques for the discovery and provenance specification of systems.

Discussion

The results show that the most popular terminologies were – SNOMED-CT covered in 82% (n=9) of the studies reviewed; LOINC in 55% (n=6) of the studies; RxNorm in 36% (n=4); and UMLS in 27% (n=3). NDF-RT was one of the less commonly used terminologies. With regards to the information standards, we found that 37% of the studies covered HL7 RIM, 31% openEHR, 25% HL7 CDA/CCR and 12% covered other standards like Intermountain CEMs or HL7 VMR. Among the studies covering the use of semantic web technologies 30% (n=3) used the ontologies for knowledge representation; 30% (n=3) used the ontologies as integration mechanisms between different conceptual models or between the EHR and the CDS logic; and 20% (n=2) used logic specification mechanism with SWRL.

Conclusion

Among all the papers we identified five main fields of work that contributed to address SiOp of the CDS systems: information standards with HL7 RIM as the most extended, SNOMED-CT as the most covered terminology, medical logic specification formalisms with the Arden syntax the most spread, knowledge management using semantic web technologies, and web services.

Development of a Mobile System Decision-support for Medical Diagnosis of Asthma in Primary Healthcare – InteliMED

Júlio Menezes Jr.[a], Cristine Gusmão[a,b]

[a] *SABER Tecnologias Educacionais e Sociais Research Group, Universidade Federal de Pernambuco, Recife, Brazil*
[b] *Departamento de Engenharia Biomédica, Centro de Tecnologia e Geociências, Universidade Federal de Pernambuco, Recife, Brazil*

Abstract

The structure of public and primary healthcare in Brazil is organized in a way to provide decentralized services. In theory, this scenario could enable the usage of mobile devices integrated with information systems of several purposes. In addition, there is a need of decision-support tools that are based on collected evidences, once the professional of primary healthcare, which essentially has general knowledge (non-specialist). Therefore there is a need of information that support the decision-making process on more specific contexts. This paper presents the proposal, experience of development and application of the InteliMED, a decision-support system to asthma diagnosis of children and adolescents through decision-trees and mobile devices (smartphones and tablets).

Keywords:
Decision-support System; Mobile Health; Case Study.

Introduction

Services of primary public healthcare in Brazil are essentially decentralized and performed by professionals that have general knowledge, once this kind of service is focused on preventive actions to the population. Considering the context of primary healthcare in Brazil, we realize that there is an organizational structure that allows the usage of mobile devices, because it works on distributed healthcare centers, in which the teams of professionals are responsible by a small part of the population and,they can perform homecare.

In this light, this work presents a proposal of medical decision-support system decentralized through the usage of mobile devices – InteliMED [1], the experience of the development of this system including a case study.

InteliMED

InteliMED is a decision-support system whose goal is to provide assistance to the primary healthcare centers for a remote support of medical diagnosis. InteliMED system aims to use decision-tree artificial intelligence technique applied to programs of communities' assistance [1].

Case Study

To evaluate the InteliMED system and its decision-tree, we performed a case study with two objectives:

1. To verify the hit rate of the generated decision-tree on the mobile application;

2.To identify points of improvement on the whole system.

InteliMED were evaluated in the ambulatory of allergy of *Hospital das Clínicas* from *Universidade Federal de Pernambuco* (HC/UFPE). The ambulatory of allergy of HC/UFPE is a specialized center of allergy and has many cases of breath allergies in children and adolescents, including Asthma. This case study was performed between June 15th and October 25th 2012 with the support of specialist doctors, in which 43 patients with ages from 5 to 18 years were consulted.

Main Results and Ongoing Work

From a total of 43 patients, the InteliMED got 36 correct and 7 wrong diagnoses (i.e., a hit rate of approximately 83,72%), which is an acceptable result. According to the opinion of the doctors, we got 25 asthmatics and 18 non-asthmatics patients.

Another interesting result is: in all the wrong diagnoses the system informed that the patient had Asthma, in which the correct result (the doctor opinion) is "No Asthma". This means that the InteliMED has been successful in all cases of non-asthmatics patients. InteliMED system brings the importance of decision-support tools in primary healthcare, concerning assistance and permanent education of healthcare professionals that work in this field.

Currently we are working on the development of educational resource for mobile devices for physical educators for older adults assessment. An initial work was developed with a group of older adults and now we are raising the system requirements.

Using Discrete Event Simulation to predict KPI´s at a Projected Emergency Room

Pablo Concha[a], Liliana Neriz[b], Danilo Parada[a], Francisco Ramis[a]

[a] *Centro Avanzado de Simulación de Procesos; Universidad del Bío-Bío, Chile.*
[b] *Departamento Control de Gestión y SI, Universidad de Chile, Chile.*

Abstract

Discrete Event Simulation (DES) is a powerful factor in the design of clinical facilities. DES enables facilities to be built or adapted to achieve the expected Key Performance Indicators (KPI´s) such as average waiting times according to acuity, average stay times and others. Our computational model was built and validated using expert judgment and supporting statistical data. One scenario studied resulted in a 50% decrease in the average cycle time of patients compared to the original model, mainly by modifying the patient´s attention model.

Keywords:

Emergency Department Design, Healthcare Simulation, KPI..

Introduction

The performance of an Emergency Department (ED) is affected by the integration of its physical design, staffing, and the equipment and service model. Inadequate design of any of these factors may result in poor future performance of the facility. Because of the complexity among the different processes and the variability present in EDs, this situation can be studied by using a DES model.

Our study was based on the use of DES tools, which are used to study KPI´s such as average cycle time, time to first medical evaluation, and utilization factor of the different rooms and resources. The model was developed using the simulation software *Flexsim Healthcare*. The methodology of the study followed seven steps: Problem formulation, Construction and validation of the conceptual model, Model construction, Verification and validation of the computer model, Design of experiments, Analysis of results and finally Documentation and presentation of results.

The flow of patients through the ED, also called carepathways, depends on the type of patient and activities which may include: admission, triage, medical assessment, treatments/procedures, diagnostic support and discharge from the ED.

A total of fourteen carepathways for the patients were defined.

1. EKG, hydration, sampling, observation
2. Nebulization
3. Intramuscular treatment, hydration, sampling
4. EKG, observation
5. hydration and sampling
6. Imaging, cast
7. Hydration, minor surgery, imaging
8. Hydration, minor surgery
9. Minor surgery, nurse procedure
10. Imaging, nurse procedure
11. Breath analysis (Example in Figure 1)
12. Medical procedure, wound treatment
13. Sampling, imaging
14. Nurse procedure

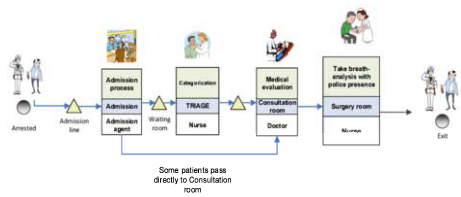

Figure 1– Sample carepathway for a breath analysis

To estimate the demand to be used in the model, the data was extracted from the database of a nearby hospital, located in the metropolitan region of Chile.

Results

The original average cycle time of patients was approximately 15 hours. The examination room was the utilization factor with the highest percentage, due to the fact all carepathways analyzed passed through this room. Additional places that showed a high utilization factor were the procedure and observation rooms, which in practice are used to perform similar activities as the examination room. Additionally, eleven of the fourteen patient carepathways passed through these rooms.

Conclusions

The simulation study conducted to analyze the future ED aided the decision making of the hospital management by allowing them to generate scenarios and analyze the possible results before implementing them. These scenarios were defined by changing the amount of stretchers in two areas and changing the attention model. Afterwards these scenarios were evaluated according to the average cycle time of the patients. The optimal reduction of cycle time of patients was the scenario where a stretcher was added in the procedure room and the attention model was changed. This decreased the cycle time from 14.8 hours to 3.7 hours in scenario 1 and the time to doctor from 11.5 hours to 1.1 hours.

Clinical Decision Support Using Electronic Medical Records: For the Improvement of Diabetes Care and Proper Use of Insulin for Inpatients

Ryoma Seto[a], Susumu Wakabayashi[b]

[a] *Division of Healthcare Informatics, Faculty of Healthcare, Tokyo Healthcare Informatics, Tokyo, Japan*
[b] *Division of Drug Information, Department of Pharmacy, Kyorin University Hospital, Tokyo, Japan*

Abstract

The aim of the study is to develop a scheme of a decision support system concerning insulin intervention for inpatients. Transaction data for 32,637 inpatients were collected from the EMR. As a result, antidiabetic agents were not taken by 38.9%–41.7% of patients with a Disease Complicated by DM. It is recommended that the EMR should provide a suggestion about insulin level for diseases with DM as a complicating factor.

Keywords:

Electronic Health Records, Drug Utilization Review, Diabetes Complications

Introduction

Diabetes prevalence is increasing in Japan, from 7.4 million in 2002 to 9.5 million in 2012. All aged ≥40 are required to have a medical checkup that includes a diabetes test. However, some patients ignore this and their condition deteriorates. The aim of this study is to develop a framework of medical information and a decision support system concerning insulin intervention for inpatients based on electronic medical records (EMR), for the purpose of preventing diabetes (DM) patients from progressing towards hemotoxic dialysis (HD).

Methods

The development was based on 3 major hospitals around Tokyo. Transaction data for 32,637 inpatients between 2009 and 2011 with regard to prescription and medical procedures related to DM were collected from EMR. Based on the data, the drug use recommendations were assessed.

Results

1) Prevalence of DM: Among the inpatients, 2.0%–3.3% had their disease registered as DM. Of all patients with DM, 21.8%–78.0% had DM, 12.6%–54.1% had a disease complicated with DM (e.g. CKD) and 9.3%–26.1% had other diseases (e.g. cancer) associated with DM.

2) Usage of Insulin and Oral Hypoglycemic Agents for all Patients with DM: Of patients with DM, 67.3%–84.3% were using insulin and/or oral hypoglycemic agents, 22.7%–28.8% of them were using only insulin, 11.0%–46.2% of them were using only insulin, and 19.2%–27.3% of them were using both insulin and oral hypoglycemic agents.

3) Drug Use of Diabetic Patients: Among the patients, 21.4%–38.9% were using only insulin, 22.7%–35.4% of them were using oral hypoglycemic agents and 32.8%–33.3% of them were using both. No antidiabetic agents were taken by only 5.6%–9.9% of patients.

4) Drug Use of Patients with a Disease Complicated by DM: 33.3% of patients were using only insulin, 16.6% of them were using oral hypoglycemic agents and 8.3%–11.1% of them were using both. Antidiabetic agents were not taken by 38.9%–41.7% of patients and 49.6% of them were not implementing self-measurement of blood glucose (SMBG).

5) Drug Use of other Disease Patients: Of patients registered as having DM, 11.5%–22.7% of them were using only insulin, 17.6%–25.0% of them were using oral hypoglycemic agents and 6.3%–47.1% of them were using both. No antidiabetic agents were being used by 43.8%–76.5% and 67.1% of them were not implementing SMBG.

6) Possibility of Uncertain Disease Registration: Of the patients implementing SMBG, those patients having DM or complications related to DM was 10.6%–29.0%.

Discussion

1) Proper Use on Antidiabetic Agent for Patients with DM: Most patients with DM were given oral hypoglycemic agents and/or insulin. The situation is a natural one because the physicians in charge are mostly specialized endocrinologists.

2) Proper Use on Antidiabetic Agent for Patients with a Disease Complicated by DM: Of patients with a disease complicated by DM, the percentage using insulin was lower than in patients with DM. However, the pathological conditions of patients with a DM complicated disease are more serious than in patients with only DM.

3) Proper Use of Other Disease Patients: With regard to patients with other diseases, some patients ignored the use of oral hypoglycemic agents, insulin and SMBG. This situation may arise from the physicians' specialty.

Conclusion

As a result of this study, we suggest that intervention via EMR is necessary to provide recommendations of insulin level for diseases with DM as a complicating factor, and any antidiabetic agents and SMBG for patients with other diseases. Information may be provided in two ways. The first is the caution in EMR for suggesting the proper use. The second is the distribution of information to physicians, pharmacists and medical officer assistants to use antidiabetic agents with the aim that more inpatients may be given antidiabetic agents. Based on the 2012 national health and nutrition examination, 26.8%–30.4% of people with suspected DM did not have DM care.

Why should I? – Acceptance of Health Information Technology Among health professionals

Joseph M.J. D'Souza[a], Inga Hunter[b]

[a] *Intensive Care Unit, Christchurch Hospital, Christchurch New Zealand*
[b] *School of Business, Massey university, Palmerston North, New Zealand*

Abstract

Applying the Technology Acceptance Model, the end user intentions to use technology applications is studied. The study finds the end users negative perception of the usefulness of the application as a major factor in its suboptimal utilisation.

Keywords:

Technology Acceptance; Health information Technology;

Introduction

Health Information Technology (HIT) and its applications have been promoted as a solution to the problems of inefficiencies, medical errors, and rising costs in delivery of health care [1]. However the benefits of the HIT on health outcomes are a product of its actual and efficient use by the clinicians [2].This research enquires into the factors influencing the clinician's intentions in the utilisation of the HIT applications. Applying Technology Acceptance Model (TAM), the extensively used model in technology acceptance studies [3], the use of the Central Line Associated Bacteraemia (CLAB) application is studied.

Methods

This study is designed as a cross-sectional quantitative study, using paper based self-completed survey questionnaire. The questionnaire is based on the instrument used by Brown, Massey, Montoya-Weiss and Burkman [4], and validated by Davis 1989 [5]. Accordingly, four variables, namely, PU, PEOU, Attitude, and intention to use the application were measured. Responses were graded on 5point Likert scale, 1 being extremely negative and 5being extremely positive. The data gathered was analysed using descriptive analyses.

Results

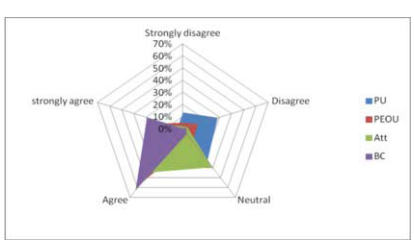

Fig.1. Average responses for all variables

Discussion

The overall findings and trends of all average responses are plotted into one graph (Fig. 1). This graph displays that the PU is the only striking outlier of all the variables with most negative responses along with a mostly neutral perception of the attitude of the users towards the application. The negative perception of the usefulness of the CLAB application and a neutral attitude towards the use of the application. The empirical evidence shows that the PU and the attitude towards use as the main factors influencing the actual use of technology [3], [5].

Conclusion

Understanding the key drivers of user acceptance of the technology and its optimal use is crucial in successful implementation of information technology, including HIT. As with other HIT applications, in order to achieve optimal use of the CLAB application it is essential to foster a positive perception of the usefulness of the application through effectively disseminating the information of its utility in achieving safer and better delivery of patient care.

Diffusion of innovation: Telehealth for care at home

Sharon Levy

Nursing Studies, University of Edinburgh, Scotland, UK

Abstract

The 'care at home' study focused on a Scottish telehealth service, which was designed to support children with palliative and complex care needs. Using the diffusion of innovation theory, this poster highlights the differences between the way telehealth is used in the public sector and in a third sector or a voluntary organization. Analysis of the data, taken from interviews with key stakeholders, illuminate barriers and solutions as noted by clinicians who see the clear benefits and potential risks of telehealth use at home. In conclusion, it is argued that a strategic steer towards a culture of innovation is needed to support effective use of telehealth in clinical practice. Senior managers in the National Health Service in the United Kingdom need to 'unleash' the goodwill of staff who are eager to exploit innovation in clinical practice.

Keywords:
Telehealth; Palliative care; Complex needs; Peadiatrics.

Introduction.

The stated aims of the study were to trial telehealth technology, setup the infrastructure and associated clinical pathways, and study the care outcomes of the children with complex and palliative care needs. We intended to explore remote care in a context where often 'high touch' rather than 'high tech' is most appropriate. The palliative care arm of the study was conducted with Paediatric Oncology Outreach teams, working in the National Health Service (NHS). The phase concerning children and young people with complex needs was supported by a third sector organisation, the Scottish Spina Bifida Association (SSBA). Whilst elements from each section of the study have been reported elsewhere (1) (2), this poster compares the outcomes of each segment and identifies potential barriers and enablers to the adoption of telehealth. The cultural differences between the organisations involved, and the impact they have on the diffusion of innovation, are considered in this study.

Methods

Clinicians across four specialist care locations were involved in data collection for this study. These included oncology healthcare teams in three NHS paediatric hospitals and a nursing team at the SSBA. At the end of the study the clinical teams were asked to reflect on their overall experience, lessons learned, and their perceptions on the way the service could be further developed. This final engagment was conducted as a face to face semi structured interview which lasted up to one hour. Interviewees included seven peadiatric outreach oncology nurses, four medical consultants, as well as two specialist nurses and an outreach worker from the SSBA. Interviews were recorded, transcribed, and analyzed for common themes, and the findings are reported here.

Results

Relative Advantage: Telehealth was introduced as a tool to enhance current services, rather than replacing them. In the NHS the potential advantages were also seen as a possible threat to future roles for staff. By contrast, the staff at the SSBA perceived the new remote service as an opportunity to affirm their key role within the organisation and cement the commitment of the organisation to continue to offer specialist nursing support to users. **Complexity**: In the NHS there is a low tolerance to the failure of clinical technology. Many interviewees noted their frustration with rigid clinical IT systems and the level of support they recived from their dedicated IT helpdesk. **Trialability**: Staff in the NHS were limited to the approved and avilable set-up, within their clinical areas, which often was a large Video Conferencing (VC) suite. SSBA staff trialed a number of technologies and opted to use SKYPE which they found easy to use. This meant that many more users were able to download the software on their own machines at home.

Conclusion

A number of attributes, aligned with the diffusion of innovation theory, served to illustrate the findings from data gathered in both the public and the third sector organizations. The plan of introducing telehealth in the complex organizations, such as the NHS in the UK, would require development of a calture of innovation. It needs a shift in organizational mindset, and a significant change in the perceptions of risks and attitudes towards failure.

Visualizing Sensor Data through an Open Platform for Connected Devices

Christian Bock[a,d], Thai Le[a], Arjmand Samuel[b], Danny Huang[b], Hilaire J. Thompson[c], George Demiris[a,c]

[a] *Biomedical Informatics and Medical Education, School of Medicine, University of Washington, Seattle, WA, USA*
[b] *Microsoft Research, Seattle, WA, USA*
[c] *Biobehavioral Nursing and Health Systems, School of Nursing, University of Washington, Seattle, WA, USA*
[d] *Ruprecht-Karls-University of Heidelberg, Heidelberg, Germany*

Abstract

Integrating sensor systems within the home can be a tedious process due to the challenges of deploying systems across multiple environments, customizing applications, and connecting across various devices. We demonstrate the deployment of sensors using the Lab of Things platform within a residence over a 3 month period. We developed a real time visualization application from the generated sensor data, and evaluated it through a survey with 19 older adults and caregivers. Findings can be a valuable guide to scale a study across multiple settings, and to create personalized interfaces.

Keywords:
Data Display; Remote Sensing Technology; Aged

Introduction

In the field of gerontology, the use of smart home sensor systems is growing primarily due to the appeal of unobtrusively monitoring older adult health and wellness. However, the deployment of sensor systems has often been limited to academic or laboratory settings. This is due to the challenges of managing multiple simultaneous installations, integrating different types of sensors, and disseminating meaningful information back to consumers. We describe the deployment of sensors within a multi-person residence using the Lab of Things platform for connected devices [1], a software platform that reduces the burden of deploying sensor systems across different environments while also serving as a central hub to manage connected devices, store data and analyze data. We developed a prototype using data collected from a smart home and integrated it into a real time visualization application.

Materials and Methods

We deployed the Lab of Things platform in a house of 11 residents as a demonstration of feasibility over the course of 3 months. The system consisted of one multi-sensor and two door/window sensors. These sensors included two Aeon Labs Z-wave Door/Window sensors and an Aeon Labs Multi-sensor that collected data on motion, temperature, luminosity, and humidity. We applied a Rapid Iterative Testing and Evaluation (RITE) approach in designing the visualizations. This involved two rounds of iterative prototyping with gerontological experts. We presented early mockups to a group of 10 gerontology experts to gather feedback and design guidelines. We then conducted a third evaluation through a survey with older adult- and caregiver stakeholders to inform further revisions to the designs. We developed the application through a combination of HTML, CSS, and JavaScript for the client side. We used a service-oriented architecture to communicate with the server machine, represented by the HomeHub on the Lab of Things platform. We evaluated the resulting application through an online survey with family members/caregivers and older adults. The survey consisted of static displays of the visualization with questions asking to rate the importance of different components of the display; such as type of data presented, ability to switch amongst different views by spatial location, and privacy concerns.

Results

Our initial mockups consisted of a bar chart representing activity level over time. A “Norm Activity Index” was provided as a reference for average activity level. We used color as an encoding for activity level relative to the norm in the bar chart. Nineteen participants completed the online survey. Family members/caregivers felt comfortable using the application indicating that they could quickly learn to use the application and would not need the support of a technical person. Older adults, however, indicated it would be difficult to learn to use the application, and had trouble identifying its utility. A key for older adults provided information on how the data collected could be utilized by their family members, physicians, or caregivers.

Conclusion

The evaluation of our application with stakeholders highlighted significant differences between how family members/ caregivers perceived of the application compared to older adults. Though family members found the application easy to learn and identified value in having the information available to monitor older adult wellness, older adults did not share this same view. Instead, they found the visualization complex and difficult to learn; partially confounded by an unclear sense of how the information could be used. This lack of perceived usability can be a significant barrier to engagement.

Automated Evaluation of Medical Software Usage: Algorithm and Statistical Analyses

Ming Cao[a], Yong Chen[a], Min Zhu[b], Jiajie Zhang[b]

[a] *School of Public Health,* [b] *School of Biomedical Informatics*
The University of Texas Health Science Center at Houston, TX, USA

Abstract

Evaluating the correctness of medical software usage is critically important in healthcare system management. Turf[1] is a software that can effectively collect interactions between user and computer. In this paper, we propose an algorithm to compare the recorded human-computer interaction events with a predefined path. Based on the pass/fail results, statistical analysis methods are proposed for two applications: to identify training effects and to compare products of the same functionality.

Keywords:

Human-Computer Interaction, TURF, Usability

Introduction

National Institute of Standards and Technology has published guidance to improve the usability of Electronic Health Records (EHR)[2], but practical software tools to archive this goal are still in the preliminary stage. Our work here was intended to provide practitioners a module of functions within TURF (task, user, representation and function), a software aiming to measure usability objectively. The current version of TURF can record user interaction such as mouse clicks and keyboard typing. The complexity of the medical applications, including EHR, usually demands a series of tasks to be completed in a pre-specified way. We defined a *path* as a sequence of human-computer interaction steps taking place in order while each step can contain possibly unordered events. An automated algorithm comparing the recorded events with a predefined standard or alternative path was needed. It saves the burden for human to watch the operation process and decide whether a user completes a task successfully or not. To analyze the results, we devised appropriate statistical methods.

Materials and Methods

Raw data were processed as following: keyboard strokes were grouped into strings, mouse clicks were associated with a widget (or window/module), and all events were indexed by their event types, element contents and attributes. Then an experiment runner could define a standard path in the following way: (1) Put several tokens into group in which order may or may not matter; (2) Insert, remove or adjust the order of steps/groups; and (3) Specify mandatory steps.We described the algorithm to compare the recorded path from a user with the standard path. To ensure the robustness of the algorithm, we dichotomized the steps into "mandatory" and "non-mandatory". The events within the mandatory steps have to take place in order and the events within the non-mandatory steps can take place without the requirement on ordering. For the non-mandatory steps, some missing events can be tolerated. Formally, a user failed if the order of steps did not match the standard path, or any mandatory step was missed. Consider two application senarios: the first could quantify how much a training session improved the average rate of correctly operating the software. To make more accurate inference, bootstrap [3] is used to estimate the variance of the log odds ratio estimator. The second scenario is to compare two EHRs that serve the same purpose but operate on two different platforms. A typical setting is one in which groups of users are randomly assigned to product A product B and then the Generalized Linear Model is applied [4]. We adjusted for other covariates using the collected demographic information.

Results

We converted system events data into a readable series of steps. A binary indicator ("pass" or "fail") to the end user was produced for the task. For users who failed the test, we highlighted the problematic area for their future improvement as well as the percentage of completing the task. Finally, an estimate of training effects or the difference of products could be given, as well as the uncertainty and statistical significance.

Conclusion

The automated evaluation algorithm we proposed makes large scale usability tests accessible to TURF users. Our in house statistical functions can quantify the training effects and product differences. The contribution we wish to make is offering the usability improvement community a ready-to-use software, rather than developing a new theory.

Abstract

To improve UX of EMR/EHR, the screen design principles for the visualization are required. Through the study of common attributes of medical records, we present four principles and show three screen designs by applying them.

Keywords:
Information visualization, UX, electronic medical records.

Introduction

Improving User Experience (UX) of EMR/EHR is important for the performance and safety of the medicine. The visualization of medical records is a pivotal problem for the implementation [1], and it should be improved by the establishment of principles based on information visualization. We discuss the screen design principles for visualizing medical records and their practical use.

Methods

Information visualization is based on the common attributes of data [2][3][4]. What are them in medical records? Each medical record has the patient whom it is about. If it loses its patient attribute, it is not clinically useful. Time is fundamental for medical care, and all medical records have their own time attribute. Types of medical records constitute the hierarchical structure in toto. First hierarchy of types is most efficient for categorizing all records. We name it primary type which is a comon attribute of medical records.

How useful these common attributes are for the screen design? To avoid confusing patients, multiple patients should not display simultaneously. In information visualization, medical records are categorized into temporal data which are frequently visualized by time-series as it is usually most efficient [2][3]. The hierarchical structure is visualized by the tree which needs two dimensions for visualization and is difficult to coexist with time-series on screen. It is not suitable that medical records are visualized by the whole types of them. But primary type is not hierarchical and can combine with time-series.

Also, information visualization can be achieved by transforming and abstracting data [4]. Thus detailed medical data should be shown by other views such as popups.

Results

From the above discussion, we propose following screen design principles for visualizing medical records. First, one view should contain single patient's data. Second, data should be deployed in time-series. Third, data should be categorized by primary type. Fourth, data should be abstracted for overview and details should be given on-demand.

By applying these principles, at least three screen designs are plausible (see Figure1). Design1: Data are arranged in the time-series and labeled by primary type. Design2: Data are arranged in matrix that has two axis: time-series and primary type. Design3: Data are arranged in the time-series, and selecting one of the points of time-series, data at the selected point of time are shown as popup which is categorized by primary type.

Figure1 – Three screen designs

Conclusion

The discussion clearly tells that medical records have the common structure for visualization. This fact gives us expectation for the universal UX of EMR/EHR. To prove the assumption, it is necessary to apply above mentioned designs to existing EMR/EHR and evaluate the feasibility of the information visualizations.

User-centered design to develop clinical applications. Literature review

Daniel Luna[a,b], María Quispe[a], Zulma Gonzalez[a], Alfredo Alemrares[a,c], Marcelo Risk[a], Mauro Garcia Aurelio[a], Carlos Otero[a]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*
[b] *ITBA, Instituto Tecnológico de Buenos Aires*
[c] *DMICE, Oregon Health & Science University, Portland, Oregon, USA*

Abstract

User-centered design is mentioned by Norman as "the need for a design that uses the natural properties of the individuals, exploiting the relationships and constraints and focusing on the needs and interests of the user, in order to make the final products usable and understandable". This is also important in health developments. The objective of this paper is to search and analyze articles in the healthcare field where user-centered design principles have been applied. We describe findings in this topic from articles published between January 1995 and September 2014.

Keywords:

User center design, electronic health record, Health information systems, Usability.

Introduction

The concept of user-centered design (UCD) has become popular in recent years due to the importance and impact that its application has had on creating more usable products.

UCD is about the need for a design that uses the natural properties of the individuals, exploiting the relationships and constraints, and focusing on the needs and interests of the user, in order to make the final products usable and understandable. The difficulty and complexity in the design of software tools for the health field has generated the need for specially trained teams to handle the particular domain. The objective of this paper is to search and analyze articles in the healthcare field where user-centered design principles have been applied.

Materials and Methods

Pubmed, Lilacs, and ACM Digital Library were used. **Inclusion criteria:** Publications that reviewed the domain related to health applications and that referred to pieces of software. Also, if human, social, and behavioral principles were taken into account in designing the user interface. **Exclusion criteria:** Domain not related to health care, development of hardware that does not include software development, and no description in the article of the process and the techniques used. **Search strategy:** We decided to use truncation strategies. The search – whenever possible – was performed using the term "user center* + design". In instances where it was not possible to use truncation strategies, we performed the search using key phrases ("User center design" / "user centered design"). Search was conducted for publications in PubMed, Lilacs, and ACM Digital Library. We established a time frame for articles published between January 1995 and September 2014.

Results

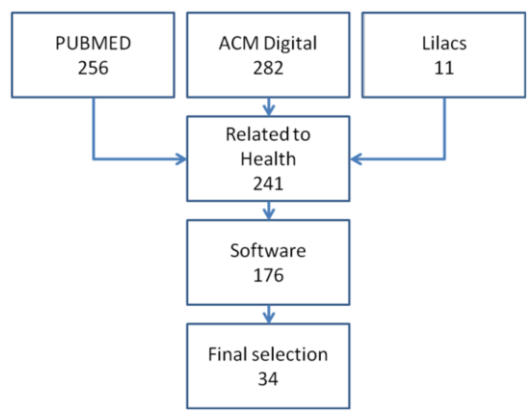

Figure 1: Flowchart with items founded.

For more detailed in the artiles analyzed see Annex 1.

Conclusion

UCD can increase the adoption and efficient use of IT tools in the field of health, reducing support, development, and maintenance cost, and ultimately increase user satisfaction and patient safety.

A Model for Usability Evaluation for the Development and Implementation of Consumer eHealth Interventions

David Parry[a], Philip Carter[a], Jane Koziol-McLain[b], Jacqueline Feather[b]

[a] *School of Computer and Mathematical Science, Auckland University of Technology, Auckland, New Zealand*
[b] *Faculty of Health & Environmental Sciences, Auckland University of Technology, Auckland, New Zealand*

Abstract

Consumer eHealth products are often used by people in their own homes or other settings without dedicated clinical supervision, and often with minimal training and limited support – much as eCommerce and eGovernment applications are currently deployed. Internet based self-care systems have been advocated for over a decade as a way to reduce costs and allow more convenient care, and – because of the expectation that they will be used to reduced health cost –, by increasing self-care and avoiding hospitalization.

However, the history of consumer eHealth interventions is mixed, with many unsuccessful implementations. Many consumer eHealth products will form part of a broader complex intervention, with many possible benefits and effects on both individuals and society.

This poster describes a model of consumer eHealth assessment based on multiple methods of usability evaluation at different stages in the design and fielding of eHealth systems. We argue that different methods of usability evaluation are able to give valuable insights into the likely effects of an intervention in a way that is congruent with software development processes.

Keywords:
Consumer eHealth; Usability; Evaluation

Introduction

This paper argues that usability evaluation – in particular, observation based approaches that include investigation of the goals and characteristics of the users, and their responses to the intervention, along with the socio-technical aspects of the application – can form part of a structured trial and development approach. Frameworks for complex interventions to improve health have been defined previously. Complex clinical interventions may include software artefacts along with system redesign and behavioral change elements.

Multiple methods of usability evaluation have been shown to be effective in detecting usability issues that arise in eHealth applications. Moreover, usability evaluation before, during, and after implementation of eHealth systems has been shown to be important and useful. The usability of so-called "consumer" health products is particularly important. Consumer products are often used by people in their own homes or other settings without dedicated clinical supervision.

The use of phases in usability evaluation, just as with pharmaceutical development, emphasises the use of low-cost evaluation methods at early stages, often reducing the number of candidate interventions drastically.

Materials and Methods

TABLE 1**:** SEQUENCING OF ACTIVITY

Stage	**Domains**		
	Pharma [19]	*Complex Intervention[1]*	*Usability*
Pre-clinical	Animal testing	Theory	Requirement gathering
Phase I	Toxicity testing	Modelling	Pre-artefact testing.
Phase II	Efficacy testing	Exploratory	In vitro
Phase III	Comparison with existing treatment	Definitive Randomized Controlled trial	In vivo Experiments
Phase IV	Post- Licensing -	Long term Implementation	Benefits Redesign

A phased evaluation model should allow the early abandonment of unsuccessful designs, and the refinement of early designs before they enter the next phase. Table 1 demonstrates the analogous phases of pharmaceutical trials, complex interventions, and usability evaluation. Table 2 illustrates the corresponding usability activities during these phases.

TABLE 2

Stage	**Usability activity**		
	Evaluation techniques	*Expected outcome*	*Usability task*
Preclinical	Interviews, observation	Types of users, Goals, tasks	Requirement gathering
Phase I	Lo-fi prototyping, Heuristics	Interface design	Pre-artefact testing.
Phase II	Usability experiments	Task completion	In vitro
Phase III	Experiments and ethnographic approaches	Practical issues	In vivo Experiments
Phase IV	Surveys, feedback	Usefulness, effectiveness	Benefits, Redesign

Results

We are currently evaluating these approaches in the context of internet- and mobile-based approaches for reduction of intimate partner violence.

Usability Analysis Of A Customized Documentation System For Nurse Population-Health Managers

Lincoln Sheets MD[a], Zhijian Luan[a], Tina Dillon[b]

[a] *PhD candidate, University of Missouri Informatics Institute, Columbia, MO, USA*
[b] *MEd candidate, University of Missouri School of Information Science & Learning Technologies, Columbia, MO, USA*

Abstract

The University of Missouri's population health management pilot employs 22 Nurse Care Managers (NCM) to manage medical casework for approximately 10,000 patients. We studied the NCMs' documentation system to identify interruptions to their clinical workflow, and identify missing functionality. We used an interview script and Morae software to observe and record five NCMs at work, measuring time on task, click counts, and task completion. We also documented quantitative and qualitative responses to a directed interview. All tasks were completed satisfactorily, with completion times of 443±275 seconds and click counts of 58±23. Surveys on a scale of 1 (worst) to 5 (best) scored "ease of use" at 3.4±1.1, "integration of functions" at 3.0±1.2, and "ease of learning" at 2.6±1.5. Overall, the system is functional and reliable but could be improved to support workflow.

Keywords:

Nursing Informatics; Computer Systems Evaluation; Managed Care.

Introduction

The University of Missouri's population health management pilot employs 22 Nurse Care Managers (NCM) to manage medical casework for approximately 10,000 patients. Halfway through the three-year pilot project, questions had begun to arise about the usability of the NCM documentation system. We conducted formal usability testing in order to identify specific workflow impediments and identify missing functionality.

Methods

We observed six Nurse Care Managers at their work and used Morae usability testing software to record their keystrokes, mouse movements, and mouse clicks. We also used an interview script to gather qualitative results, and five of the volunteers completed a three-item questionnaire after the test.

Results

Time on task and clicks needed

Statistic	Time (sec)	Clicks
Minimum	180	25
Maximum	920	108
Mean	443	58
Standard Deviation	275	23

Survey results (from 1=worst to 5=best)

Statistic	Q1 (ease of use)	Q2 (integration of functions)	Q3 (ease of learning)
Minimum	2	2	1
Maximum	5	5	5
Mean	3.4	3.0	2.6
Std. Dev.	1.1	1.2	1.5

Conclusion

Overall, the LIGHT^2 NCM Documentation system was functional and reliable, but we found these specific problems:

- Organization: the screen order often didn't reflect the variation in clinical encounters.
- Functionality: needed functions were present, but users had to exit the system to view related records.
- Usefulness: the users didn't find the system to be clinically useful, but saw this is a consequence of its purpose rather than a design flaw.

We can also make these general recommendations, which may be generalizable to other population-management system documentation systems:

1. Consult system users on content organization, size of fields, and order of screens.
2. Allow flexibility in re-ordering screens when appropriate.
3. Link the nursing documentation system to the related electronic medical record without exiting and re-entering.
4. Enable notes to be labeled, dated, and searched.
5. Improve performance to decrease the initial load time.
6. Add auto-correction or spell-check to text-entry fields.

Digital Inclusion for Older Adults based on Physical Activities: an Age Concern

Cristine Gusmão[a,b], Júlio Menezes Jr.[a], Carmelo Pina[c], Juliana Lima[a,b], João Barbosa Neto[a,b]

[a] *SABER Tecnologias Educacionais e Sociais, Universidade Federal de Pernambuco*
[b] *Departamento de Engenharia Biomédica, Centro de Tecnologia e Geociências, Universidade Federal de Pernambuco*
[c] *Prefeitura da Cidade do Recife*

Abstract

Nowadays, we are living in an interdependent and interconnected world during an age that is driven by technological progress. It has extraordinary potential to improve the quality of later life: creating social networks to tackle isolation and loneliness; transforming services to help people live independently at home for longer; empowering consumers; and enabling civil participation. In light of this, this poster aims to present the development process of a digital booklet for mobile devices – smartphones and tablets that illustrate the benefits of doing physical exercises for older adults aiming to improve life quality and minimizing digital exclusion.

Keywords:

Older Adults; Physical Exercises; Digital Inclusion.

Introduction

The main barrier of using computers and the internet among older people appears to be a lack of understanding and confidence with 'how it works'. People struggle to comprehend how to use the actual equipment and require explanation as to 'what to press and when' [1].

The benefits of physical activity practice are not restricted to physical-functional and mental field of individuals, but also to social, improving functional performance, maintaining and promoting the independence and autonomy of the older people. Especially among the elderly, it has been found that physical activity decreases the risk of institutionalization and the use of health services and medications [2].

Despite a low level of understanding about how information and communications technology (ICT) can be used, knowledge of its potential benefits is surprisingly high in older people population. From this perspective, this poster presents a project about the development of a digital booklet that will be used to allow older people technological initiation and digital inclusion approaching information about the gains of physical exercise.

Materials and Methods

All methodological actions were planned for integration with extension activities to academic proposals and involved a group of students (undergraduate and posgraduate).

1. Literature review: for understanding the state and progress of current literature on older people health and well being by organizing, integrating, and evaluating previously published books and articles, specially from Brazilian Ministry of Health.

2. Practical habilities: visits were made to the older people group who practice physical activities under Professor Carmelo Pina's supervision. The group consisted of about 50 elderly women, 60 to 90 years, who are under regular medical supervision. The main goal of this phase was to integrate the theoretiical versus practical concepts. All the students attended the activities and contributed to a technical report.

3. Questionnaire application: the questionnaire was applied to a group of 30 elderly women. The main results were: (i) average age: 68,7; (ii) previously read booklets (26); (iii) information gathering location: newspapers (18), magazines (10), and internet (13); (iv) how difficult was it to use new technologies: very easy (1), easy (8), medium (9), hard (10), or very hard (3); (v) internet usage: daily (6), weekly (10), biweekly (2), monthly (1), or almost never (5); (vi) favorite colors: blue and red; (vii) not favorite color: black.

4. Booklet development and testing: the process involved: (i) booklet content writing: after analysis of the group, we selected the following subjects: Mobility, Resistance, Balance and Motor Coordination. (ii) graphic design: using the questionnaires results for the definition of booklet layout; and (iii) user interfaces and application engine: development of the digital booklet through web technologies (HTML5).

Partial Results and Ongoing Work

The use of mobile technologies universalizes and stimulates people's access to health practices. In this case, the elderly population for which it is to exercise more, greatly improving their quality of life. Thus, through the application of educational, older people will be presented with the opportunity to: (i) review concepts and fundamentals of situations and teaching and learning conditions, inserting them and acclimatizing them in the current and future reality of the elderly; and (ii) work the social, psychological, and health (physical and mental) of the elderly.

Development of the eHealth Literacy Assessment Toolkit, eHLA

Dorthe Furstrand[a, b], Lars Kayser[a]

[a] *Department of Public Health, University of Copenhagen, Denmark*
[b] *Danish Cancer Society Research Center, Denmark*

Abstract

In a world with rising focus on the use of eHealth, the match between the competences of the individual and the demands of eHealth systems becomes increasingly important, thus making assessment of eHealth literacy as a measure of user competences a vital element.

We propose the eHealth Literacy Assessment toolkit, eHLA, evaluating the user by seven scales: computer familiarity, confidence, incentive and performance as well as functional health literacy, health literacy self-assessment and health literacy performance, as a first step toward development of technology that accommodates the literacy level of the user.

Keywords:

Self-Assessment; Ehealth; Telemedicine; Computer Literacy; Health Literacy; Information Literacy; Patient Participation.

Introduction

Digital health services have become an integrated part of modern healthcare, exposing a growing range of individuals to the challenges of using and benefitting from such systems. For eHealth to be valuable, it is imperative to look at the match between the abilities of the intended user and the skills needed for relevant use of the technology. If a mismatch is to be met, an assessment of user competences, as embraced by the concept of eHealth literacy, must be made. The objective of this project was to develop an assessment tool for this purpose. Health literacy is described as the ability to manage health information in order to maintain and promote good health [1], and eHealth literacy expands the term to include the digital aspect of seeking, finding, understanding, appriasing and applying health information [1]. The Lily Model of eHealth literacy as proposed by Norman and Skinner in 2006 [1] defines the concept by six sub-literacies: traditional, information, media, health, computer and scientific literacy, together providing a frame for describing many of the aspects of competences needed. Since this model, the way we use digital services has changed, and communication, collaboration and content generation takes a larger part. The model of eHealth Literacy by Norgaard [2] is created through a grounded approach taking in both the user and the system perspective. Five out of seven domains hold the view of the user; including knowlegde about one's own health, ability to interact with information and with technology, drive to engage with technology and feeling in control and secure when using technology.

Methods

The foundation of eHLA is an appraisal of predominant methods of assessing health literacy and digital literacy, and the aspects evaluated. eHLA originates from a toolkit used by Knudsen et Vang [3] for eHealth literacy and usability assessment of COPD patients, and was expanded to map up to the Lily model and the Norgaard model, as frameworks of eHealth literacy. The iterative development process included workshops, cognitive interviews and a small scale pilot test of the toolkit.

Results

The seven tools included in eHLA, as seen in Table 1, take care to evaluate self-assessed competences, drive for engagement and comfort, as well as performance, thus sculpting the toolkit around the two models.

Table 1 – Tools included in eHLA

The 7 eHLA tools
Digital literacy tools
Computer Familiarity
Computer Confidence
Computer Incentive
Computer Performance
Health literacy tools
Functional Health Literacy
Health literacy Self-assessment
Health Literacy Performance

Conclusion

The eHLA toolkit showed promising preliminary results for all but one tool, Computer Performance, making it ready for further testing and adjustment, which is now underway.

eHLA and eHealth literacy assessment will enhance the knowledge of user abilities, thereby aiding digital health services in being applicable and beneficial to all patients, thus contributing to the bridging of the social divide in health.

Type 1 Diabetes in Twitter: Who All Listen To?

Elia Gabarron[a,b], Alexandra Makhlysheva[a], Luis Marco[a,b]

[a] *Norwegian Centre for Integrated Care and Telemedicine, UNN, Tromsø, Norway*
[b] *Faculty of Health Sciences, Department of Clinical Medicine, The Arctic University of Norway, Tromsø, Norway*

Abstract

Knowing what the conversation on Twitter regarding type 1 diabetes (T1D) is about can help in understanding the kind of information relevant to the individuals affected by the disease. The profile of Twitter users posting on T1D was collected and classified. The number of re-tweets was also registered. The tweets posted by non-governmental organizations (NGOs), communication media, and individuals affected by T1D had higher number of potential readers. More than a half of the tweets were posted by individuals affected by T1D, and their tweets were the most re-tweeted. The next most active users were NGOs and healthcare professionals. However, while tweets soliciting for research funds posted by the NGOs were the next most re-tweeted messages, tweets posted by healthcare professionals were the least re-tweeted. Twitter could be used more actively by healthcare professionals to disseminate correct information about T1D.

Keywords:
Type 1 Diabetes Mellitus; Social Media; Twitter Messaging.

Introduction

Prevalence studies estimate around 500,000 children aged under 15 years have type 1 diabetes (T1D) worldwide [1]. These children and their parents might be looking for information on the disease online, especially on social media, since it has become one of the first sources of information about health [2]. As other diseases, T1D is one of the widely discussed topics on social media.

The aim of this study is to describe the profile of Twitter users posting about T1D, and the potential relevance of the tweets, based on the number of re-tweets and followers.

Materials and Methods

In December 2014, we searched Twitter to sample in total 300 random tweets containing the hashtags #type1diabetes, #t1d, or #type1. Information regarding the tweets emitters, as well as the number of re-tweets were collected. The tweet emitters were classified into six categories: individuals affected by T1D (either patients or parents of children with T1D); healthcare professionals; non-governmental organizations (NGOs); information websites; journalists or communication media; and private companies.

Results

The 300 downloaded tweets on T1D were potentially read by 549,676 readers, according to the number of followers of the emitters at the moment the tweets were posted. Tweets posted by NGOs, communication media and individuals affected by T1D had higher number of potential readers: 210,086; 122,232; and 90,084 respectively.

Most of the tweets from individuals affected by T1D were personal experiences or reccomendations; while tweets from NGO solicited funds for research. Details on the number of tweets per type of emitter, as well as the frequency of re-tweeted messages are summarized in Table 1.

Table 1 – Tweets and re-tweets by user profile

Tweet emitter nature	Tweets on T1D	Re-tweets
Individuals affected by T1D	160 (53.3%)	241 (47.8%)
Non-governmental organizations	37 (12.3%)	139 (27.6%)
Healthcare professionals	36 (12.0%)	14 (2.8%)
Private companies	32 (10.7%)	46 (9.1%)
Communication media	19 (6.3%)	36 (7.1%)
Information site	16 (5.3%)	28 (5.6%)
TOTAL	**300 (100%)**	**504 (100%)**

Conclusion

Individuals affected by T1D are the main group of Twitter users posting about the disease. The personal experiences and reccommendations shared by individuals affected by T1D seems to be the most interesting topic for other Twitter users. The next most active users were NGOs and healthcare professionals. However, while tweets posted by NGOs soliciting research funds were the next most re-tweeted messages, tweets posted by healthcare professionals were the least re-tweeted. Twitter could be used more actively by healthcare professionals to disseminate correct information about T1D.

Characterizing Consumer Health Informatics in Low and Middle Income Countries

Tugba Kutun[ab], Miriam Föller-Nord[a], Thomas Wetter [bc]

[a] Dept of Computer Science, Mannheim Univ of Appl Sci, Germany, [b] Inst for Medical Biometry and Inform., Heidelberg Univ, Heidelberg, Germany, [c] Dept Biomed Inform and Medical Educ, Univ of Washington, Seattle (WA) USA

Abstract

Consumer Health Informatics (ConsHI) involves patients in health care through ICT, with Low and Middle Income Countries recently entering the field. Compelling successes and complete failures call for the identification of success factors. Of 1092 automatically retrieved articles, 85 were classified as ConsHI. Their service characteristics and the economic and societal factors of the countries of origin were classified. Descriptive statistics were applied in the search for clusters of features that together appear as driving factors. Most factors (financial endowment, number of languages spoken etc) showed no or paradoxical effects. Societal maturity and low population density appear as enabling factors.

Keywords:
Consumer Health Informatics, Low and Middle Income Countries

Introduction

ConsHI offers preventive or medical services through ICT and patient empowerment, driven by the shortage of clinical workforce, opportunities to reach underserved populations at distant locations and the benefits of patient buy in. In a 2014 investigation [1] we looked at the expectations for ConsHI in Low and Middle Income Countries (LMIC). Drawing on paradigmatic examples, we suggested project-internal and environmental success factors. [1] pointed to tentative factors now addressed more broadly.

Material and Methods

PubMed articles were searched with a "Core" process as in [1] for *SMS, cell phone,* etc. and then manually sifted. For active countries with >= 1 confirmed finds, we added a "Ceiling" search with advanced tech terms *Internet, smart phone,* etc. and checked the sifted finds for features (medical problem, service type). Active countries' features were taken from the World Bank web site. A 5-tier classification of the 125 poorest countries (per capita Gross Domestic Product, pcGDP) was applied as in [1] (tier 1 = poorest). In tier analysis, hypotheses for low activity in tiers 3/4 were tested. Next, correlations between numbers of articles and country features were calculated using ranks (r) for clearly non-Gaussian features.

Results

Of 1092 retrieved articles, 85 were considered ConsHI in Core or Ceiling. 31 from India and China are excluded in Table 1b due to their huge populations' distorting effects, leaving 24 countries. A paradox from [1] of lowest activity in tiers 3 and 4 is confirmed for Core (Table 1a). Adding Ceiling makes 3 the single lowest. 7 countries in tiers 3/4 are one of the 15 former USSR republics. Table 1b shows the strongest correlations with article numbers in PubMed (subsequently: Activity). The negative correlations insinuate that low geographical latitude and low population density are enabling factors.

Table 1a – Activity by tier

Tier	Core	Ceiling
5	16	2
4	9	13
3	5	0
2	25	1
1	11	3

Table 1b – Activity vs feature

Country Feature	Corr. Coeff.
Distance to equator	-0.36
Internet users (r)	0.36
Female literacy	0.30
Population density	-0.27
Languages	0.26

Table 2a – Service types

Service type	Core	Ceiling
Prevention	21	2
Therapy	17	12
Follow up	11	0
Education	4	8

Table 2b – Medical problems

Condition	# Art.
HIV	28
Mental disorder	11
Bacteria/Parasites	9
Diabetes mellitus 2	9

Prevention ranges from dental hygene to safe sex. Many therapies are drug reminders. Depression and suicide lead the Mental list. Richer media in Ceiling benefit Education (Table 2).

Discussion

The small sample size limits the validity of conclusions and the results resist easy explanations. Closeness to the equator and thus attracting development aid suggests itself. More widely, if money helps, International investment or Increase in pcGDP should correlate with Activity. Number of cell phones should also correlate, but neither does. Internet usage, Female literacy and Tourism suggest a societal maturity "Gestalt". Low population density fosters services that cover distances. Method as in [2] may substantiate such claims.

Conclusion

The lack of common success factors found here supports the service-to-context fit proclaimed in [1] as prevailing factor.

3D CPR Game Can Improve CPR Skill Retention

Jia Li[a], Yimin Xu[a], Yahong Xu[a], Peng Yue[a], Liu Sun[a], Ming Guo[a], Shuqin Xiao[a], Shu Ding[a], Yanyan Cui[a], Shulan Li[a], Qiuying Yang[b], Polun Chang[c], Ying Wu[a,*]

[c] *Institute of biomedical informatics, National Yang-Ming University, Taiwan*

Abstract

Adequate cardiopulmonary resuscitation (CPR) skill is essential in improving survival rate of sudden cardiac arrest (SCA). However, the skill deteriorates rapidly following CPR training. We developed a computer game by using 3-Dimensional virtual technology (3-D CPR game) for laypersons in the purpose to improve skill retention. As the testing phase, a randomized control trial, in which we recruited 97 freshman medical students who had no prior CPR training experience, was used to test its effect on 3-month CPR Skill retention. The usability of the game was also tested using a 33 item questionnaire rated with 5-point Likert scale. Three months after the initial CPR training, the retention rate of CPR skill in the game group was significantly higher compared with the control ($p<0.05$) and the average score on 4 dimensions of usability were 3.99-4.05. Overall, using 3-D CPR game in improving CPR skill retention is feasible and effective.

Keywords:

CPR; 3-D computer game; skill retention; Cardiac arrest

Introduction

SCAs are usually occurred in out-of-hospital settings (OHCA). Bystander CPR is an effective way of improving the outcome of OHCA. However, the survival rate depends on the quality of bystander's CPR skill which could deteriorate quickly even at 2 weeks after training [1]. Although our previous study showed that remote supervised reinforcement of CPR skills by telephone could improve CPR skill retention, adherence was poor. Because game can provide a learning-by-playing environment and motivate trainees, we designed a 3-D CPR game for laypersons to refresh CPR skills and improve skill retention. This pilot study was to test the effect and the usability of the game by recruiting freshman medical students who had no prior CPR training experience, therefore provide evidence for further usage of CPR game in improving skill retention among a larger population of laypersons.

Materials and Methods

3-Dimensional virtual technology and real-world scenario were used to develop a CPR computer game. After repeated modification and trial use, freshman medical students who had no prior CPR training experience were recruited and randomly assigned into game or control group using sealed envelopes if they pass the test after AHA basic life support *Heartsaver* course. Subjects in the game group were instructed to play the game to approach a victim and provide resuscitation according to the CPR skill they learned, while control group were told to refresh their skills frequently. Three months (±2 weeks) following the CPR training, all the subjects who had passed the initial examination were invited to return for re-examination on Resusci Anne manikins which can printout data on volume of ventilation, rate and depth of compression, and compression site. The usability of the game was also evaluated on a 5-point Likert scale questionnaire, which was developed according to Technology Acceptance Model of Davis, F. D. (1989). The content validity for the total scale was 0.95 and the Cronbach's alpha was 0.98.

Results

The interfaces of the final CPR game are shown in Figure.1. There are two avatars (one SCA victim and one rescuer). The player can control the rescuer avatar by computer mouse and keyboard to act as a rescuer to perform CPR as learned during the CPR training course.

During the testing phase, 97 subjects were recruited and finished the study. The 3-month retention rates of overall performance, compression depth, airway opening, and ventilation volume were higher in the game group compared to the control ($p<0.05$). The average score on 4 dimensions of usability scale for this game were 3.99-4.05.

Figure.1 - Resuscitation game interfaces

Conclusion

Using 3-D CPR game in improving CPR skill retention is feasible and effective among freshman medical students who had no prior CPR training experience, and the effect for laypersons needs to be further investigated in a wider range of population.

Improvement of Hemoglobin with Repeated Health Checks Among Women in Bangladesh

Mariko Nishikitani[a], Yasunobu Nohara[b], Partha Ghosh[c], Rafiqul Islam Maruf[c], Ashir Ahmed[a,d], Naoki Nakashima[a,b]

Abstract

The residents of several cities and villages in Bangladesh underwent e-health checkups. The distribution of Hb increased from the first hemoglobin (Hb) measurement to the second, and some women recovered from severe anemia. A strong effect was observed in subjects who were prescribed iron supplements. The mean blood pressure improved after the first health examination, and the blood sugar level increased. In countries with shortages of health practitioners and health care providers, e-health examinations and instructions may be useful interventions because they make people health conscious and improve their health status.

Keywords:

Preventive medicine; E-health; Health examination; Hemoglobin (Hb); Women; Developing countries

Introduction

In developing countries, low hemoglobin (Hb) suggests inferior health and nutritional status and indicates risks for increased maternal and child mortality. If Hb information is provided it may help prevent disease development and death.

In this study we checked Hb level as part of a general health examination in Bangladesh. The objective of this study was to assess the effect of the health examination and the subsequent health instructions on Hb levels in women.

Methods

E-health checkups were provided for the residents of Dhaka, five villages, and employees in several factories/offices in Bangladesh during 2012 and 2013. Individual health measurements were recorded automatically and diagnosed based on international diagnostic standards. Tele-consultation and tele-prescription were provided [1].

The first checkup at several venues of six cities in 2013 included 10,575 subjects (5,043 women, 48%). The study subjects were the 1,205 women who had abnormal Hb levels at their first checkups. Two months later, a second checkup was conducted in five cities and some venues, and 348 women returned.

Results

The mean baseline Hb of the returning group (n = 348) was 10.8 ± 1.7 g/dL and it did not differ significantly from that in women seen only at the first visit (n = 857, 11.0 g/dL). The mean Hb at the second checkup among the returning group increased to 11.5 ± 1.3 g/dL (Figure 1). Blood pressure decreased by 4–5 mmHg. Body mass index (BMI) did not differ significantly between checkups, and blood sugar increased significantly when comapred with the first visit.

To confirm the effect of health instructions following the first checkup, several interventions were assessed, including suggested prescription drugs, prescribed iron (Fe) supplements, dietary instructions, and referrals to specialists. The standardized partial regression coefficient adjusted for age, job, and place of checkup showed that the prescription of Fe supplements had a significant positive effect on Hb (beta = 0.325, $p < 0.001$).

Conclusion

Repeated health examinations and subsequent health instructions were useful interventions that improved Hb and other health indicators among women in Bangladesh.

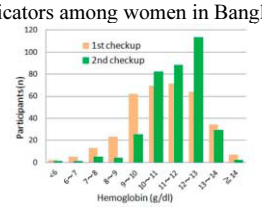

Figure 1 – Change in the distribution of measured Hb

Cardiac auscultation simulator embedded in virtual learning environment to support medical teaching

Isaias Oliveira[a], Zilma Silveira N Reis[a], Marilene M Araújo[b], Claudia Maria V Freire[b]

[a] School of Medicine, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil
[a] Prenatal care service for cardiac diseases, Hospital das Clínicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Abstract

Heart auscultation remains as an important clinical tool in heart disease diagnostics. A prototype was developed, using an existing database of clinical and cardiac sounds of pregnant women [1]. The context for virtual learning is cardiac disease during pregnancy (Partum and Post Partum situations). Based on real histories, cardiac sounds, and complementary exams, this pilot presents the most frequent diagnosis of cardiac diseases during pregnancy.

Keywords:

Heart Auscultation; Digital Stethoscope; Cardiovascular Pregnancy Complications; Medical Informatics, Teaching Materials.

Introduction

Heart auscultation is a highly important clinical tool in diagnosing hearts diseases [2]. However, this detection is still a challenge for professionals who work directly in prenatal health care. It is estimated that most internal medicine and family practice physicians are not able to recognize common heart sounds and murmurs that could be diagnosed using a stethoscope [3].

This study presents a cardiac auscultation simulator using virtual learning environment.

Methods

The simulator was projected to support teaching of cardiac auscultation. The institution's Ethics Committee approved the study, and all volunteers signed a letter of consent.

From the methodological approach of problem-based learning, real clinical patients are the starting point. The purpose is intended to cause the student to be challenged, and therefore active in the learning process, encouraging them to study the desired content. The interface was developed to be intuitive and self-explanatory, with minimal adaptation time.

Results

The system model has a main screen with a female thorax (Figure 1), data collection, and an interactive area interface. Heart sounds sequence took place in the classic areas of auscultation.

While listening to the audio, the student can choose to view patient data. The challenge for students is to reach the true diagnosis of a cardiac disease, choosing from a list of four options.

Discussion/Conclusion

Simulation environments can contribute by allowing repetitive and individualized oriented training in support of learning in real scenarios [4].

In this work, we present a functional prototype system of learning to provide training for normal and abnormal cardiac auscultation.

Global Challenges in People-Centered E-Health

Yuri Quintana, Charles Safran

Division of Clinical Informatics, Beth Israel Deaconess Medical Center and Harvard Medical School

Abstract

People-centered health care seeks an active role for the patient while empowering all other members of the health care team. By promoting greater patient responsibility and optimal usage, patient-centered health care leads to improved health outcomes, quality of life and optimal value for health care investment. This paper reviews some definitions of people-centered health care and various e-health approaches around the world used to implement this vision. The barriers and enablers to implementation this type of approach are explored. This paper provides a proposed research agenda for future implementations of people-centered e-health.

Keywords:

Person-centred health care; participatory health; health services research; individualized care; complex systems; transdisciplinary research; people-centered e-health.

Introduction

It has been long argued that "the largest and yet least used health care resource, worldwide, is the patient or prospective patient" [1-4]. In recent years, technology has helped to provide patients a greater voice in how health care is accessed and delivered. People-Centered Health Care medicine [5] is a model of medical care in which the active role of the patient is emphasized. The overall vision for people-centered health care is one in which individuals, families, and communities can participate in trusted health systems that respond to their needs in humane and holistic ways. People-centered health care is an umbrella term that better encapsulates the foremost consideration of the patient across all levels of health systems. The definition of people-centered health care has shifted over the years, and the implementation has also shifted; however, the core values have remained the same.

Methods

We searched the PubMed using the search query ("people-centered" or "patient-centered" or "people-centred" or "patient-centred" or "participatory medicine") and ("patient empowerment" or "patient participation" or "family engagement" or "social justice") in titles and abstract, searched the Internet with the same terms. We then reviewed websites and publications and summarized the objectives, approaches and outcomes of some of the frequently cited programs in the areas of patient empowerment, patient participation, family engagement, and social access.

Conclusions

People-centered health care programs [1-9] provide an opportunity to promote patient empowerment, patient participation, family engagement, and social justice. Some programs have shown some promising results by showing increasing numbers of patients using the programs but the evidence on outcomes is still limited. Most of the programs are in developed countries. Some international guidelines have been developed for these programs. This paper has proposed some strategies for the design and implementation of programs in developing countries. More research is needed for how to design and evaluate these programs in different settings and cultures. Patient representatives should be part of product design teams, health care provider committees, and in government policy committees so that programs that are created support patient priorities.

Use of Patient Portals: Personal Health Information Management in Older Adults

Anne Turner[ab], Katie Osterhage[b], Jonathan Joe[a], Andrea Hartzler[c], Lorelei Lin[b], George Demiris[a]

[a] *Biomedical Informatics & Medical Education*
[b] *Health Services, University of Washington, Seattle, WA USA*
[c] *Group Health Research Institute, Seattle, WA USA*

Abstract

The personal health information management (PHIM) of older adults is poorly understood. We describe initial results from the SOARING (Studying Older Adults & Researching Information Needs and Goals) study at the University of Washington, a particpatory design investigation of PHIM in older adults. We conducted in-depth interviews with older adults (n=71) living in a variety of residential settings. A surprising 21% of participants reported using patient portals. Another 17% of participants reported prior use or anticipated use of portals in the future. We identified preferences and needs as well as barriers and facilitators to portal use. Our findings indicate that patient portals designed to target the specific needs for older adults can suport PHIM. We offer recommendations for expanded research.

Keywords:

Patient portals; Older adults; Health information management.

Introduction

Older adults have been slow to adopt technologies such as patient portals for managing their personal health information (PHI). A patient portal is a secure website through which patients access information from an electronic health record. These technologies are largely designed without consideration of older adult needs and preferences. Understanding the barriers and uses of technology by older adults for PHIM can inform design imporvements. In the context of a broader project to investigate PHIM in older adults, we report on general computer use and the use of patient portals among older adults across different residential settings.

Methods

We conducted 71 in-depth interviews with older adults aged 60 years (yrs) and recruited from adult residential centers, assisted living, and independent residences in King County, WA USA. We used purposive sampling to ensure diverse representation of gender, socio-economic status (SES), and racial backgrounds. The interviews assessed participant demographics, health, social networks and technology use, followed by open-ended questions regarding PHIM practices. We transcribed and coded interviews for emergent themes.

Results

Participants described PHIM practices ranging from complex systems of medication tracking to discarding all but the most critical health information. Of all participants, 65% (46/71) reported using a computer at least 2-3 days/week, and a majority, 79% (56/71), reported access to the Internet. A portion of participants, 21% (15/71), mentioned current use of patient portals, while another 17% (12/71) of participants had previously used a portal, used a portal through a family member, or indicated potential future use. Current portal users ranged from age 61 to 93 yrs, most lived independently, and responses indicated middle to high SES. The majority felt positive about the specific portal they used, which were primarily versions of Epic MyChart™ (Epic Systems Corp, Verona, WI). Several participants mentioned a dramatic reduction in their health information record keeping because of the portal. One participant reported disconituation of the portal due to log-in frustrations.

Discussion

Despite reports of barriers to the use of PHI technologies by older adults, 21% of the older adult participants use patient portals to manage personal health information. This trend is encouraging for the future. However, the small number of participants who use portals (n=15) in this study limits our ability to analyze the effect of age and living situation on portal adoption. Expanded research is needed to determine the general penetration of patient portals in this population, factors that contribute to portal use by older adults, and associations between portal use, age, and living situation.

Conclusion

Study findings highlight the small, but substantial, role of patient portals as a platform to facilitate management of PHI. The use of patient portals demonstrates their potential role in helping older adults to maintain wellness and independence.

Machine Assisted Translation of Health Materials to Chinese: An Initial Evaluation

Anne M. Turner[a], Loma Desai[a], Kristin Dew[a], Nathalie Martin[a], Katrin Kirchhoff[b]

[a] *Department of Biomedical Informatics and Medical Education*
[b] *Department of Electrical Engineering, University of Washington, Seattle, WA, USA*

Abstract

There is an unmet need for Chinese language health materials in the USA. We investigated the use of machine translation (MT) plus human post-editing (PE) to produce Chinese translations of public health materials. We collected 60 documents that had been manually translated from English to traditional Chinese. The English versions were translated to Chinese using MT and assessed for errors and time required to correct via PE. Results suggest poor initial translation may explain the lack of quality translations despite PE.

Keywords:
Public health informatics; natural language processing; machine translation, Chinese language, health promotion.

Introduction

Chinese is the second most common language among limited English proficient (LEP) individuals in the USA. LEP status has been associated with negative health consequences, including poorer health outcomes and poorer access to health care. Unfortunately, due to the time and costs of producing quality translations, very few health materials are available in languages other than English. Our previous research indicates that free online translation engines, such as Google Translate, can be used in conjunction with human post-editing (PE), to produce quality English to Spanish translation quickly and at low cost. To investigate the usefulness of MT in translating health materials for a more difficult language pair, we investigated the types of errors in English-to-Chinese machine translations, the PE time to correct them, and the quality of MT plus PE compared to manual translation.

Methods

We collected 60 health promotion documents from various public health websites and conducted three stages of experiments with them: linguistic error analysis, PE, and quality rating. Five native Chinese participants with health experience performed PE. We recorded the time taken to PE each document. Two bilingual public health professionals then independently, blindly rated a subset of 20 pairs of manually translated and MT-plus-PE documents to indicate which they preferred and why.

Results

The linguistic error analysis found that word sense errors were most common (40%), followed by word order errors (22%) and missing words (16%).

PE time as measured by the mean charaters/min CPM per document varied from 18.5 to 79.6 CPM (SD = 0.03-38.7). The mean CPM across all documents was 38.9 (SD = 9.9); thus, on average a post-editor can correct approximately 39 CPMs with a variation of around 10 CPMs. There was no relationship between document length and post-editing time. PE participants rated the adequacy of the MT output at 3.6, suggesting that "much" to "most" of the original meaning of the source text was preserved with MT. The average fluency was rated 3.4, which indicates a level of grammar quality between "non-native Chinese" and "good Chinese". There were large differences in PE speed between post-editors, ranging from 18 to 41 CPM.

In the blind comparison of MT plus PE and manual human translations, both quality raters preferred the manually translated document in all 20 cases. Reasons given for the preference were better word order, professional reading level, flow, word accuracy, and cultural appropriateness.

Discussion

Although our prior research using English to Spanish translation indicated that MT with PE could produce a translation equivalent in quality for less time and cost, translation from English to traditional Chinese showed that maintaining quality through post-editing was more problematic. The final post-edited translations still contained errors that made the quality rater prefer manual translations. There are several possible reasons for this difference including: differences in MT quality for this language pair; differences in instructions provided to post-editors; linguistic expertise of post-editors; engagement of post-editors; and subtleties of cultural appropriateness.

Conclusion

Despite great need, there are few health promotion materials available in Chinese. Our investigation of the use of MT plus PE to produce translations indicated that using the methods that worked for English-Spanish translations were not as effective for English-Chinese. Multiple factors, including the quality of the MT and the expertise of the post-editors, may contribute to this result. We are performing additional studies to determine how best to improve translation from English to Chinese in order to ensure quality translation at low cost.

Lessons Learnt from Evaluation of Computer Interpretable Clinical Guidelines Tools and Methods: Literature Review

Soudabeh Khodambashi[a], Øystein Nytrø[a]

[a] *Department of computer and Information Science, Norwegian University of Science and Technology, Norway*

Abstract

Representation of clinical guidelines in a computer interpretable format is an active area of research. Various methods and tools have been proposed which have been evaluated based on different evaluation criteria. The evaluation results in the literature and their lessons learnt can be a valuable learning resource in order to redesign and improve the tools. Therefore, this research investigates the lessons learnt from the evaluation studies. Broad search in literature together with a purposeful snowball method were performed to identify the related papers that report any type of evaluation or comparison. We reviewed and analysed the lessons learnt from the evaluation results and classified them into 17 themes which reflect the suggestion concerns. The results indicate that the lessons learnt are more focused on tool functionalities, integration, sharing and maintenance domain. We provide suggestions for the area which had less attention.

Keywords:

Computer interpretable clinical guidelines; Evaluation; Lessons learnt.

Introduction

Clinical guidelines mostly are written in a free-text format from which it is hard to search and retrieve recommendations during medication in a short period of time. Several improvements with respect to computer interpretable clinical guidelines (CIGs) have been reported [1]. Some of the tools and methods were evaluated based on sets of criteria independently in order to assess the extent to which the tool can satisfy certain aspects [2]. As each of the evaluations and their results are valuable and much can be learned by comparing the findings, the main goal of this research was reviewing the results of evaluations studies and their lessons learnt regarding both technical and sociotechnical aspects in the domain of CIGs.

Methods

The research method was literature review in the domain of CIGs. We searched in the Journal of Biomedical Informatics, Journal of the American Medical Informatics Association, Methods of Information in medicine, International Journal of Medical Informatics, Artificial Intelligence in Medicine and Digital Bibliographic Library Browser to find the relevant papers. The search keywords were "computer interpretable guidelines", "clinical guideline formal representation", "electronic clinical guideline", and "computerized clinical guideline". In addition, a purposeful "snowball" sampling method enabled us to gain more relevant papers which were cited in the full-text of the reviewed papers.

Results

A total number of 27 papers identified as relevant for full-text review. We grouped similar results into 17 thematic categories. The similarities are identified based on their suggestions for improvement in specific domain. The identified themes are: user support in modelling and encoding process, standard terminology and data model, consistency checking, knowledge specification step, guideline content and dimensions, visual support and editor features, variation, ontology and semantic tagging, macros, representation on different level of abstraction, representation primitives, automatic knowledge extraction, concurrent guideline development and formalization, configurable component-based modelling constructs, required skill levels, tool functionality, didactic and maintenance support.

Discussion

The results indicate that lessons learnt are more focused on functionalities that a tool needs to support, as well as integration, sharing and maintenance considerations (i.e. standard terminology and data model). In addition, factors that reduce variability and improve consistency of the encoded guidelines are another area of concern. We see fewer suggestions related to visualization support, especially regarding adaptation to the encoder's skill level. Based on the results, visualization support with provided didactic material that is adapted based on user's skills can improve usability and reduce variability in encoding clinical guidelines.

Conclusion

The results of this paper are valuable for researchers and designers of the tools in the domain of CIGs. To our best knowledge, this is the only broad literature review on the results and evaluation lessons in the domain of CIGs.

The need for cost-benefit analyses of eHealth in low and middle-income countries

Fleur Fritz[a], Mihiretu Kebede[b], Binyam Tilahun[a]

[a] *Institute of Medical Informatics, University of Münster, Germany*
[b] *Department of Health Informatics, University of Gondar, Ethiopia*

Abstract

Cost and benefit analyses are crucial for eHealth interventions, especially in low and middle income countries (LMIC). We performed a scoping review, with goals to acquire an overview of cost-benefit studies and to collect indicators that are being used for costs and savings with respect to eHealth. Of all retrieved articles, 29 were included in our analysis and 21 contained cost/savings indicators which we categorized into outcome measures with respect to providers, patients and other stakeholders. Nearly all authors stated that more evidence from economic analyses by health economists are urgently needed and that pilot projects should collect cost related data for evaluation.

Keywords: *E-health; cost-benefit; efficiency; low-income*

Introduction

Many LMIC face the challenge of providing medical care with limited resources. During the last decade there has been an increase in the use of health information technology (HIT) to support medical work [1]. However, if LMIC want to empirically decide on which eHealth application is worthwhile for countrywide use, they are largely dependent on small and scattered pilot installations, oftentimes without thorough evaluations. Many of the pilot studies that are being conducted report on the feasibility of the implemented systems, but analyses on impact and cost efficiency are largely missing [2]. Despite this clear deficit, in a setting in which there is insufficient funding to provide adequate medical staffing for basic medical care, the decision to use resources for IT must be well-justified. Our objective in this study therefore is to provide an overview on current research about eHealth interventions in LMIC with respect to cost-benefit analyses.

Materials and Methods

We conducted a scoping review by searching the PubMed database and respective reference lists. In the analysis we collected all direct or indirect mentioned cost and savings indicators. The indicators were mapped according to Schweitzer et al.'s outcome measures for mhealth (originally derived from Davalos et al. [3]) [4].

Results

Our search resulted in 90 articles, of which 29 were included according to our inclusion criteria. Of the 29 articles, 15 were evaluation studies, 10 review papers, 3 lessons learned and 1 use case. Not all analysed articles explicitely named cost and savings indicators. From 21 we were able to extract a total of 50 measures. In a consensus process we removed redundant indicators, while renaming and merging common variables. This process resulted in 32 distinct cost and saving indicators. We then compared the collected indicators with Schweitzer et al.'s measures of clinical and social outcomes from patient, provider and stakeholder perspectives [4].

The results show that eHealth applications primarily benefit healthcare providers in terms of data quality, service improvement and paper cost savings. Second, they benefit other healthcare stakeholders by improving communication, and reporting, and remote patient monitoring. Third, they benefit the patient by reducing travel and and waiting times, in addition to improving diagnostic accuracy and clinical efficiency.

Discussion & Conclusion

Although the number of implementations, and consequently evaluations and review papers on eHealth in LMIC are increasing, evidence on cost-benefit, particularly from a patient's perspective, is lacking. There is an urgent need to perform economic analyses to effectively use the limited available resources in LMIC. A validated framework for economic analyses of eHealth interventions is still lacking. In order to develop suitable methodologies and validate HIT evaluation frameworks in the context of developing countries, the HIT community should join forces with economists.

Effects of electronic prescription on pharmacy productivity

Reima Suomi[a], Markus Lähteenoja[b] and Sirpa Peura[c]

[a] University of Turku [b] University of Turku [c] Association of Finnish Pharmacies

Abstract

Electronic prescriptions affect pharmacy workflows. In this study, we measure the workflow efficiency in pharmacies in 2006 and 2012: both, in traditional workflow when electronic prescription was not in use, and in new direct delivery workflow, which is the mandated workflow model in the case of electronic prescriptions.

Keywords:

Electronic prescription, pharmacy productivity, retail pharmacy, community pharmacy, outpatient pharmacy, pharmacy workflow

Introduction

Electronic prescriptions have been widely used in Finland during 2012 – 2014. A switch to electronic prescription changes the counter delivery in the pharmacies from a workflow that we call "traditional model" to a new one that we call "direct delivery model". In this research we study what this change means to the productivity of the Finnish pharmacies.

Methods

In the research, we measured the interaction time needed to take care of one prescription at the counter of retail pharmacies. The process started from the customer entering at the counter, and ended with the handout of the medicine. Payment time for the medicine was not included.

Measurements were taken at two timepoints: in years 2006 and 2012.The year 2006 results have been reported elsewhere [1], and are not a topic of this presentation. The detailed results of the 2012 study are reported in [2]. Methodologically our research is quite close to traditional Taylorism.

Results

Detailed data on the delivery processes is in Table 1.

Table 1. *Number of prescription delivery processes analyzed in 2006 and 2012*

	Paper prescription 2006	**Paper prescription 2012**	**Electronic prescription 2012**
Customer sessions	123	347	162
Number of prescriptions handled	190	573	275
Number of packets delivered	234	704	322

Table 2 contains the needed times for medicine delivery.

Table 2. *Total times of delivery for different prescriptions in 2006 and 2012*

	Paper prescription 2006	**Paper prescription 2012**	**Electronic prescription 2012**
median time	2 min 38 s	1 min 43 s	2 min 4 s
average time	2 min 48 s	1 min 58 s	2 min 26 s
standard deviation	1 min 34 s	57 s	1 min 17 s
minimum time	34 s	32 s	36 s
maximum time	12 min 40 s	6 min 22 s	9 min 15 s

In general, medicine delivery process in pharmacies has improved during the timespan of 2006 – 2012, making the prescription handling times faster.

Discussion

E-prescriptions have not increased pharmacy productivity. Time needed to handle an electronic prescription is down by 13% from year 2006 figures. However, the improvement in handling time is even better (30%) for the paper prescriptions.

Conclusion

In the Finnish environment, the results show that with the electronic prescription, the delivery time for a single medication over the counter was cut by 13%. In other words, the pharmacists are able to deliver 10 prescriptions in the same time that previously allowed nine prescriptions to be handled. This Indicates that productivity in pharmacies has grown a lot during the studied time period in Finnish pharmacies.

(Br-SCMM) Brazilian Smart City Maturity Model: A Perspective from the Health Domain

Ricardo Alexandre Afonso[a,b], Kellyton dos Santos Brito[a,c], Clóvis Holanda do Nascimento[b], Luciana Campos da Costa[a], Alexandre Álvaro[b,d], Vinicius Cardoso Garcia[b]

[a] *Alagoas Federal University (UFAL), Arapiraca AL, Brazil*

[c] *Pernambuco Federal Rural University (UFRPE), Recife PE, Brazil*
[d] *São Carlos Federal University (UFSCar), Araraquara SP, Brazil*

Abstract

The term definition "Smart City" still allows various interpretations, and this causes some difficulty in establishing parameters to measure how smart the cities can be. This paper presents a Maturity Model that uses a set of minimum domains and indicators that aim to encourage cities of different sizes to identify their potential and improve processes and public policies.

Keywords:

Public health; Big Data; Government; Smart Home.

Introduction

The concept of Smart Cities is still confused. Some authors suggest the use of scenarios related to transportation, health, technology, infrastructure, stability and others [1,2]. The purpose of this work is to present a way to measure how smart a city can be. In addition, to propose an incentive mechanism for cities to come to the ranking of the Smart Cities emphasizing the domain Health of these cities; and what indicators can be used to make this comparison between municipalities.

Methods

To create the rating for smart cities, the attention on creating minimum measures which may be affected by these smaller municipalities is needed. Therefore, this work proposes to create a model composed of ten areas called "Domains Basic" where each domain has its respective "Basic Indicator" [3].

Table 1 – Basic Domains and Indicators

Basic domains	***Basic Indicators***
A. Water	Piped water
B. Education	HDI-Education
C. Energy	Access to energy
D. Governance	HDI Employment
E. Housing	Private residence
F. Environment	Garbage collected
G. Health	HDI, ISO37120
H. Security	Homicides per 1000
I. Technology	Computer at home
J. Transportation	Mass transit

Results

The model proposed in this work was called Br-SCMM (Brazilian Smart Cities Maturity Model). It uses the domains and indicators presented in results of this study to measure the first level on a scale from 1 to 5 to identify possible areas for improvement before that the following levels are adopted. The levels are divided into five categories that compose the word (SMART): Simplified, Managed, Applied, Measured and Transformed. All Brazilian capitals were measured using the S level of this model.

Conclusion

This work presented the domains and indicators that will be used to measure the capacity optimization and improvement of municipal resources and processes. The model (Br-SCMM) is being developed in partnership with three Brazilian universities and the municipalities where these institutions are located so that you can implement and test the following levels of this model.

Factors Influencing Consent for Electronic Data Linkage in Urban Latinos

Suzanne Bakken[a,b], Sunmoo Yoon[a], Niurka Suero-Tejeda[a]

[a] *School of Nursing, Columbia University, New York, NY, USA*
[b] *Department of Biomedical Informatics, Columbia University, New York, NY, USA*

Abstract

Within the context of patient participation in a Learning Health System, this study examined consent rates and factors associated with consent for linking survey data with electronic clinical data in a sample of 2,271 Latinos. Consent rate was 96.3%. Government insurance status and health literacy significantly influenced the odds of consent.

Keywords:

Learning Health System; consent; Latinos

Introduction

In the United States (US), as well as elsewhere, there is an increasing emphasis on the Learning Health System (LHS), which is enabled through a digital infrastructure. In its recommendations for the LHS, the Institute of Medicine highlighted the need for broader data capture and re-use[1]. A key component of the LHS is a fabric of trust (i.e. the willingness of individuals, and by extension, society, to contribute personal data and clinical experiences to the development of an LHS). However, it is difficult to build a strong fabric of trust among racial and ethnic minorities as reflected by low participation rates in research studies, low participation rates in biobanks, and limited use of information technologies for health-related purposes.

In previous research, we examined the sociodemographic factors and health factors that influenced consent for collection, storage and use of biospecimens in four contexts, with varying consent rates (53.2%-58.0%), in a sample of Latinos (n=2,290) who participated in the Washington Heights Inwood Informatics for Comparative Effectiveness Research (WICER) survey. Particpants were compensated with $10 for a saliva specimen and $15 for a dried blood spot. Government insurance and immigrant status increased the likelihood of consent in all contexts; higher health literacy increased the likelihood of consent for general use and long-term storage as compared for use by WICER team.

The purpose of this study was to address another decision made by individuals at the time of survey participation, which is relevant to the fabric of trust for the LHS, consent for linkage of survey data with electronic clinical data for research purposes. Two research questions were addressed: 1) Do consent rates for data linkage differ from those for biospecimen collection, use, and storage? 2) What sociodemographic and health factors are associated with the decision to link survey and electronic clinical data?

Materials and Methods

As part of the WICER survey in a primarily Latino immigrant community in New York City, a community health worker asked Latinos if they were willing to have their survey data linked with electronic clinical data. We examined factors associated with consent through logistic regression.

Results

In the sample of 2,271 Latinos, the consent rate for data linkage was 96.3%. This was significantly different than consent rates for all contexts of biospecimen use with Chi-square ranging from 78.6-92.8 ($p<.001$). Variables that met the criterion for entry into the logistic regression ($p<.2$ in bivariate analysis) were government insurance status, health status, hypertension, and health literacy. Gender, age, education, and immigrant status were not entered. Only two variables were significant: government insurance (OR=.332[.442-.775], p=.011) and health literacy (OR=1.35[1.09-1.67], p=.006).

Conclusion

Overall consent rates were high, suggesting a positive contribution to advancing the fabric of trust for a LHS. However, in contrast to our previous work on biospecimen consent, those with government insurance (Medicare or Medicaid) as compared to private insurance, a measure of socioeconomic status, were less likely to consent to linkage of survey data with electronic clinical data. Further work is needed to elucidate the role of financial incentives versus other factors in influencing Latinos to participate in LHS activities.

Communication problems between end-users and technicians through a Help Desk in a Health Information System

Gabriela Garcia , Agustina Bertoia , Leonel Cameselle , Sonia Benitez , Diego Giunta , Analía Baum , Fernán Gonzalez Bernaldo de Quiros

Hospital Italiano de Buenos Aires, Argentina

Abstract

Communication between users and technicians is crucial for improving Help Desk performance. The objective of this study is to know and understand perceptions, and needs of users and help desk technicians. A qualitative study based on interviews was performed. The emergent topics were communication, workload and misperceptions between end-users and technicians. There are false perceptions between them that affect their interaction and work dynamics.

Keywords:

Qualitative research; perceptions; service support; Health information system

Introduction

End-users of Health Information Systems (HIS) must have adequate support and training to ensure proper HIS use. Adequate support requires human and technological resources capable of serving, managing and solving all of the possible problems, and good interpersonal communication skills between users and technicians is needed. Support and training are important components of HIS implementation but procedures, challenges and lessons learned are under-represented in the literature. A lack of support in complex scenarios like health care organizations may interrupt workflow causing dissatisfaction and impact in patient care. However, little is known about how end-users and technicians perceive their roles, their commitment and how they face communications challenges using a Help Desk (HD). The objective of this research is to understand end-users and technicians insight about their role in the support process.

Methods

Setting

In 1998 the Health Informatics Department (HID) of Hospital Italiano de Buenos Aires (HIBA) started the development and implementation of an HIS. The HID has 150 members from different disciplines. The computational infrastructure consists of 4,000 personal computers and 1,500 devices (printers, scanners, tablets) available for almost 8,000 users. Users can request support using an online HD. Each request generates a ticket that facilitates problem tracking. When the problem is solved, the user receives a survey by email to give feedback about the support.

Design

A Qualitative study based on in-depth interviews was conducted between March and September of 2014. Content analysis was performed using Grounded Theory and NVivo 10.

Results

Eighteen users (nurses, physicians, other professionals and administrative personnel) and fifteen HD technicians were interviewed. The emergent topics were: communication, workload (including perception of workload, priority of tasks, type of problem, type of end-user, feedback), and misperceptions between end-users and technicians. The most important are communication and misperceptions.

Technicians say they need to contact the user who made the request due to lack of information in the ticket description; highlighting the importance of verbal communication with the user. *Users* also believe it is better to communicate by telephone with technicians before requesting support because they doubt that it is well written or they feel there is a lack of information to explain the problem.

The *technicians* have the perception that users: (1) think their requests have high priority; (2) do not cooperate to be located easily; (3) are dissatisfied with the delay on ticket resolution; (4) do not value the technicians' work, because users do not give any feedback. On the other hand, *users* have the perception that the technicians do not try to communicate with users. However, users recognize that is difficult to be found because of the work dynamics, and understand that the delay in resolution is due to the HD workload. Finally, users admit that they do not value the technicians' work enough.

Conclusion

Users and technicians are the main actors in the HD process. To ensure good support of an HIS, it is necessary to implement communication strategies to remove barriers that create false perceptions.

Speech therapy teleconsultations of a public telehealth service in a developing country

Aline Moreira Lucena[a], Maria Beatriz Alkmim[a], Vinícius Soares Garcia[a,b], Erica de Araújo Brandão Couto[b], Milena Soriano Marcolino[a,b]

[a]*Telehealth Center, University Hospital, Universidade Federal de Minas Gerais; Telehealth Network of Minas Gerais, Brazil*
[b]*Medical School, Universidade Federal de Minas Gerais, Brazil*

Abstract

Our aim is to assess speech therapy teleconsultations performed by the Telehealth Network of Minas Gerais, a public telehealth service that attends 722 cities in Brazil, to demonstrate the importance of the telehealth to support these professionals. In this observational retrospective study, consecutive speech therapy teleconsultations performed by the Telehealth Network of Minas Gerais, Brazil, from February 2011 to May 2014, were analyzed. Socio-demographic characteristics of the cities which requested teleconsultations were assessed, and teleconsultations were analyzed based on the type of query. Throughout the study, 259 valid speech therapy teleconsultations were performed. There were no significant differences in socio-demographic characteristics of municipalities that requested and did not request speech therapy teleconsultations. Speech therapists (65%), nurses (27%) and physicians (5%) requested the highest number of teleconsultations, mostly related to the area of language (47%), oral motor skills (29%), voice (20%), audiology (18%) and dysphagia (10%). In conclusion, teleconsultations demonstrated to be a potential tool for speech therapists working in remote areas.

Keywords:
Speech Therapy; Telemedicine; Public Health

Introduction

In Brazil, there is a high concentration of the healthcare professionals and resources in the largest cities. The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service that connects six university hospitals with primary care of 722 remote municipalities performing teleconsultations in several health specialties. The speech therapy teleconsultations began in TNMG since 2011. The objective of this study was to assess speech therapy teleconsultations performed by the Telehealth Network of Minas Gerais. A public telehealth service which attends 722 cities in Brazil, to demonstrate the importance of the telehealth to support these professionals.

Materials and Methods

This retrospective observational study assessed all consecutive teleconsultations performed by the TNMG, from February 2011 to May 2014. The teleconsultations were classified according to the professional who requested and the specialist who answered them. Socio-demographic characteristics of the cities which requested teleconsultations were also assessed.

Results

Throughout the study, 259 valid speech therapy teleconsultations were performed. Among the 668 cities attended by the TNMG, 81 requested at least one teleconsultation (12%). A comparative analysis of socio-demographic characteristics of users and non -users municipalities is shown on Table 1.

Table 1 – Socio-demographic characteristics of the cities

Variables	Users (n=81)	Non users (n=587)
Total population (x1,000 inhabitants)	6.40 (4.21-9.27)	6.724 (4.43-11.80)
HDI	0.66 (0.62-0.68)	0.66 (0.63-0.70)
Income per capita (USD)	231.31 (178.54-306.14)	252.15 (198.60-311.24)
% of poor	17.50(9.69-32.98)	17.53(9.22-26.98)

FHP: family health program, HDI: human development index. P-value was >0.05 for all variables.

Speech therapists (65%), nurses (27%) and physicians (5%) requested the highest number of teleconsultations. Regarding the type of query, 19% were educational, and 81% were related to the assistance of a particular patient. Of these, 35% were about diagnosis and 65% for discussion of procedures and therapeutic approaches. The questions were mostly related to the area of language (47%) and oral motor skills (29%), followed by voice (20%), audiology (18%), dysphagia (10%) and public health (3%). There was no significant relation between the professional category of the professional who requested the teleconsultation and the type of query.

Conclusion

Teleconsultations demonstrated to be a potential tool for speech therapists working in remote areas. The use of teleconsultations in speech therapy is still incipient, and the results indicate that there are no socio-demographic differences that justify the limited use of teleconsultation. We believe that the service must be more promoted to speech therapists that work in remote municipalities.

Teleconsultations to Provide Support for Primary Care Practitioners and Improve Quality of care – the Experience of a Large Scale Telehealth Service in Brazil

Milena Soriano Marcolino[a,b], Julia Pereira Afonso dos Santos[a,b], Daniel Santos Neves[a], Maria Beatriz Moreira Alkmim[a]

[a]Telehealth Center, University Hospital, Universidade Federal de Minas Gerais; Teleheatlh Network of Minas Gerais, Brazil
[b]Medical School, Universidade Federal de Minas Gerais, Brazil

Abstract

This observational restrospective study was designed to assess teleconsultations performed by a public telehealth service in Brazil. A satisfaction survey was used to assess the impact on clinical practice. A total of 63,975 teleconsultations were performed, from April 2007 to November 2014. Family physicians (33%) and dermatologists (19%) answered most queries. From January to February 2014 (n=895), the most frequent queries were about etiology (30%) and pharmacological treatment (25%). The satisfaction survey in 2014 (n=571) showed that teleconsultations avoided patient referal in 78%. This study aims to shows the potential of telehealth to provide support to primary care practitioners in remote cities.

Keywords:

Telehealth, Public Health, Primary Healthcare.

Introduction

In Brazil, there is a high concentration of healthcare professionals and resources in the largest cities [1]. Telehealth was implemented to reduce this inequality in healthcare. The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service which connects six university hospitals with primary care units in remote cities. Since 2007, the network has been performing teleconsultations (second opinion) for a broad range of medical and non-medical specialties. The TNMG currently attends primary care practitioners in 722 cities [2].

The objective of this study is to assess the teleconsultations performed by the TNMG, in order to demonstrate the importance of telehealth to support these healthcare professionals, as well as promote continued education.

Methods

In this retrospective observational study, all teleconsultations performed between April 2007 and November 2014 were assessed and classified by both the requesting professional and the responding specialist. The teleconsultations were analyzed based on the type of query. A satisfaction survey was applied in the end of each teleconsultation to assess the impact on clinical practice.

Results

The study reviewed 63,975 teleconsultations that were performed. The healthcare professionals who requested the highest number of teleconsultations in the last 12 months were nurses (46%) and physicians (42%). The response time was under 24h for professionals on duty (family physicians, dermatologists, nurses, speech therapists, physiotherapists, dentists, psycologists) and under 48h for subspecialists. Family physicians (33%), dermatologists (19%), nurses (13%), obstetricians and gynecologists (10%), pediatricians (7%) and dentists (4%) answered the most queries. From January to February 2014 (n=895), 81% of the queries were related to patients' assistance and 19% were theoretical queries. The most frequent queries were about etiology (30%), pharmacologic treatment (25%), propedeutics (12%), non-pharmacologic treatment (12%). According to the ICD-10 classification, the majority of the queries were about skin and subcutaneous tissue diseases (16%), infectious and parasitic diseases (11%), digestive (8%), genitourinary (7%), cardiovascular (5%) and endocrine (5%) diseases. The satisfaction survey in 2014 (n=571) showed that teleconsultations avoided patient referal in 78% of cases, and 95% of the users were satisfied with the service.

Conclusion

This study shows the potential of telehealth to provide support and promote continued education for primary care practitioners in remote locations, as well as improving the access of the Brazilian population to specialized care.

Clinical Quality Control of a Large-Scale Teleconsultation Service

Maria Beatriz M. Alkmim[a], Milena Soriano Marcolino[a,b], Junia Xavier Maia[a,b], Cristiane G. Pessoa[a], Elaine Machado[a], Lidiane Sousa[a]

[a]*Telehealth Center, University Hospital, Universidade Federal de Minas Gerais; Teleheatlh Network of Minas Gerais, Brazil*
[b]*Medical School, Universidade Federal de Minas Gerais, Brazil*

Abstract

The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service in Brazil that assists 722 municipalities in the state of Minas Gerais. As a large-scale teleconsultation service, it was important to implement clinical quality control to guarantee the quality of the service. Our aim is to describe the audit of the teleconsultation responses performed by TNMG. A random sample was selected from teleconsultations performed by the specialists from the TNMG between January and February 2014. The responses were evaluated regarding size, objectivity, quality, ethics, courtesy and grammar. A total of 640 teleconsultation responses were assessed, and the mean scores were ≥2.45. Objectivity and quality had the lowest scores in the different specialities. The methodology was useful for evaluating the teleconsultation service and for identifying the areas to improve.

Keywords:

Telemedicine, Teleconsultation, Public Health, Quality Control.

Introduction

Telehealth has been growing rapidly worldwide. Teleconsultation is an important tool to support healthcare professionals in remote municipalities. It has high potential to improve access to healthcare and improve quality of care at reduced costs. The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service in Brazil that assists 722 municipalities in the state of Minas Gerais. As the service expands it is important to perform periodic audits to guarantee its quality. The objective of this study is to describe the audit of the responses of teleconsultations performed by the TNMG.

Materials and Methods

A random sample was selected from teleconsultations performed by the specialists from the TNMG between January and February 2014. The responses were scored from 1 to 3. Different weights were attributed to each variable according to its impact on the quality of the teleconsultation. Size was weighted by a factor of 0.5, objectivity and quality by 0.3, ethics by 0.1, and courtesy and grammar by 0.05. All medical and non-medical specialities and subspecialities were assessed. For the purpose of this study only the results of the professionals who work on duty will be shown.

Results

A total of 640 teleconsultation responses were assessed, of which 76% were medical and 24% non-medical. Of the non-medical responses, 65% were nursing, 12% dentistry, 8% physiotherapy, 6% pharmacy, 5% psychology, 3% nutrition and 2% speech therapy. Table 1 shows the objectivity, quality, ethics and courtesy scores for medical and non-medical teleconsultation responses. Scores for size ranged from 2.67 to 3.00 (medical) and 2.74 to 3.00 (non-medical), and for grammar ranged from 2.79 to 3.00 (medical) and 2.97 to 3.00 (non-medical). The final score ranged from 2.74 to 2.98 for medical and from 2.75 to 3.00 for non-medical specialities.

Table 1 – Scores for medical and non-medical teleconsultations responses

	Objectivity	**Quality**	**Ethics**	**Courtesy**
Medical	2.90	2.71	2.91	2.99
Dermatology	2.99	2.92	2.75	3.00

Audit of primary care electrocardiograms sent as emergency to a telehealth service - the Telehealth Network of Minas Gerais, Brazil

Milena S. Marcolino[a,b], Bárbara C.Carvalho[a], Aline M. Lucena[a], Ana Luiza N. França[a,b], Cristiane G. Pessoa[a], Daniel S. Neves[a], Maria Beatriz M. Alkmim[a]

[a]*Telehealth Center, University Hospital, Universidade Federal de Minas Gerais; Teleheatlh Network of Minas Gerais, Brasil*
[b]*Medical School, Universidade Federal de Minas Gerais, Brazil*

Abstract

The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service in Brazil that has performed electrocardiogram (ECG) analysis since 2005. From February to March 2014, 28% of ECGs were classified as "emergency" by the primary care tele-health sites. This quasi-experimental study aimed to investigate the reasons behind the high number of emergency ECGs being sent in, the implementation of corrective actions, and an assessment of the impact of these actions. In the 1st phase, primary care units that sent >70% of ECGs as emergency from February to March 2014 were selected. The 2nd phase consisted of the intervention. In the 3rd phase, the proportion of ECGs sent as an emergency during the 1st and 2nd months post intervention were assessed. Of the 63 cities selected during the 1st phase, 50% of the practitioners did not know the proper definition of emergency. After the intervention, 67% of the cities had a significant reduction in the proportion of ECGs sent as an emergency during the 1st month, and 17% had a significant reduction during the 2nd month.

Keywords:

Telemedicine, Eletrocardiography, Primary Healthcare.

Introduction

The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service that assists 730 municipalities in the State of Minas Gerais, Brazil. From February to March 2014, 28% of ECG exams performed by the primary care telehealth sites were classified as "emergency". Our hypothesis was that a great number of ECGs were incorrectly classified as "emergency". This is potentially harmful, as it delays the assessment of the true emergency ECGs. The objective of this study was to investigate the reasons for the primary care telehealth sites sending a higher number of emergency ECGs than expected, and to implement corrective actions in order to reduce the proportion of ECGs incorrectly classified as emergency.

Materials and Methods

In the first phase of this quasi-experimental study, primary care units that sent >70% of ECGs as emergency from February to March 2014 were selected to participate. The 2nd phase consisted of open question telephone calls to the 63 telehealth sites selected to investigate the criteria adopted to classify a case as an emergency. Primary care practitioners were informed about the criteria to classify an ECG as emergency using Brazil's Federal Council of Medicine. An e-mail with reinforcement information was also sent to each practitioner. In the 3rd phase, the proportion of ECGs sent as an emergency during the 1st and 2nd months after the intervention were assessed. Chi-square tests were performed to compare baseline, 1st and 2nd months.

Results

Of the 63 telehealth sites, nurses and nursing technicians were responsible for 92% of the ECGs performed. 50% of the practitioners did not know the proper definition of an emergency. All exams were sent as emergency by 16% of primary care professionals.

After the intervention, 67% of the sites had a significant reduction ($p < 0,05$) in the proportion of ECGs sent as an emergency during the 1st month post intervention, and 17% had a significant reduction during the 2nd month (Figure 1).

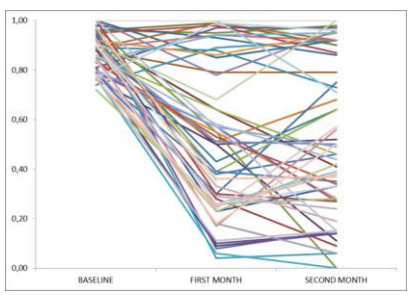

Figure 1- Proportion of ECGs classified as emergency at baseline, 1 month and second month post intervention

Conclusion

This study demonstrated that many medical professionals responsible for ECG exams at the primary care units in remote cities did not know the correct criteria definition of emergency, and that interventions as simple as a telephone call and email may be effective in reducing the proportion of ECGs incorrectly classified as an emergency.

Referring Quality Assessment of Primary Health Care for Endocrinology in Rio Grande do Sul, Brazil

Gabriela Monteiro Grendene[a], Átila Szczecinski Rodrigues[a], Natan Katz[a], Erno Harzheim[a]

[a] *TelessaúdeRS - Programa de Pós Graduação em Epidemiologia, UFRGS, Brazil*

Abstract

This paper presents results of an assessment of the quality research of endocrinology referrals in the public health system in the state of Rio Grande do Sul. From the analysis of 4,458 requests for endocrinology referrals, it was found that 15% of referrals had insufficient information for evaluation and 71% showed no clinical justification for authorization of referencing. The partial results of the study indicated that the lack of information makes it impossible to clinically regulate these requests. The use of referencing protocols associated with telemedicine tools can assist doctors in primary health care in the clinical management and make access to specialized services more equitable and timely.

Keywords:
Endocrinology; Telemedicine; Telehealth.

Introduction

The project Regulasus is a partnership between the core TelessaúdeRS / UFRGS, of the Federal University of Rio Grande do Sul (UFRGS), and the State Government of Rio Grande do Sul, that qualifies and reduces medical specialty referrals [1]. One of the biggest barriers in the internal medicine regulatory process is the lack of clinical information, which makes it difficult to evaluate the need for consultation and priority of access to health care in various specialties [2, 3]. This study aims to evaluate the quality of clinical information of endocrinology referrals. It is based on referencing protocols approved by the State Complex Governor of Rio Grande do Sul.

Materials and Methods

TelessaúdeRS / UFRGS researchers have developed referral protocols for the six most common medical conditions in the area of endocrinology (diabetes mellitus, hypothyroidism, hyperthyroidism, thyroid nodules, multinodular goiter and obesity). Based on these protocols, a medical regulator reviewed the requests, between November 2013 and December 2014, using the following classification:

- Reference with clinical justification for consultation with an endocrinologist (authorized request);
- reference without clinical justification for consultation with an endocrinologist (TelessaúdeRS consulting);
- reference without sufficient clinical information to regulation (pending for lack of information).

Results

There was a total of 4,363 regulated requests for Endocrinology. Of this total, only 621 (14%) were considered appropriate and sent for consultation, 3081 cases (71%) were referred for teleconsulting with TelessaúdeRS/UFRGS team, and 634 requests (15%) were returned to municipalities.

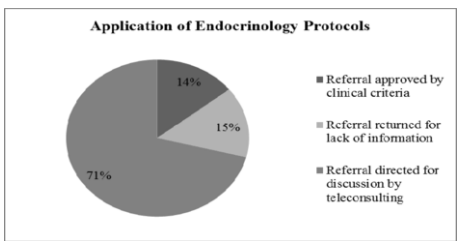

Figure 1 - Application of Endocrinology Protocols

Conclusion

The partial results of this study indicate that the lack of information makes regulation of clinical referrals difficult. Patients whose clinical management can be performed in Primary Health Care make the demand much greater than the supply, and hinder access to other patients for consultation in specialized services. The use of referral protocols can help primary health doctors by making access to care faster and more equitable.

2,000,000 Electrocardiograms by Distance: An Outstanding Achievement for Telehealth in Brazil

Milena Soriano Marcolino[a,b], Maria Beatriz Moreira Alkmim[a], Leonardo Bonisson[a], Renato Minelli Figueira[a], Antonio Luiz Ribeiro[a,b]

[a]*Telehealth Center, University Hospital, Universidade Federal de Minas Gerais; Teleheatlh Network of Minas Gerais, Brazil*
[b]*Medical School, Universidade Federal de Minas Gerais, Brazil*

Abstract

Our aim is to describe the evolution of the telediagnostic service of the Telehealth Network of Minas Gerais (TNMG), a public telehealth service in Brazil. It started in 2006 with 82 cities, restricted to electrocardiography analysis. Currently it extends to 772 cities - performing also Holter, ambulatory blood pressure monitoring and retinography analysis - and 48 ambulances in the north of the state, as part of a myocardial infarction system of care. Using low-cost equipment and simple technology, TNMG has employed various strategies to increase telehealth use. The number of ECGs performed by TNMG has progressively increased. It was expected to achieve 2 million in February 2015. The utilization rates were around 90%. It proved to be economically sound, promoting savings of 45M USD for an investment of 10.2M USD. It is currently a regular health service in the state, integrated into the healthcare system. In conclusion, the telehealth model developed in Minas Gerais produced good clinical and economical results.

Keywords:
Telemedicine; Telecardiology; Public Health.

Introduction

Minas Gerais is a Brazilian state with important social, cultural, economic, infrastructural and geographical contrasts. The Telehealth Network of Minas Gerais (TNMG) is a public telehealth service formed by 6 public universities. It performs teleconsultation and telediagnostic services, to help improve healthcare for the population who live in distant and poor regions. The objective of this study is to describe the evolution of the telediagnostic service provided by the TNMG.

Materials and Methods

This is a descriptive study. The TNMG started in 2006 in primary care services of 82 cities. It was restricted to electrocardiography analysis in primary care. Using low-cost equipment and simple technology, TNMG has employed various strategies to improve/increase telehealth use. Financial support is provided by federal, state and municipal government. The service keeps an online technical support for the villages. The utilization rates are monitored by a specialized team. Progressive expansions were performed to other cities and other levels of care. New applications were developed and validated, to increase the exams performed - such as Holter, ambulatory blood pressure monitoring and retinography analysis. A new tele-electrocardiology application to use in Androids was also developed, to increase usability in ambulances. All applications are in Java, interoperable, and data is compacted into a database (PostgreSQL). Technology and maintenance methodology are constantly evaluated and improved. Periodic audit is implemented to assure quality of the ECG analysis.

Results

The TNMG currently extends to 772 of the 853 cities of the state, including 4 secondary care units, 7 emergency care units in Belo Horizonte, the state's capital, and 48 ambulances in the north of the state, as part of a myocardial infarction system of care. The number of ECGs performedwere expected to reach 2 million in February 2015. During the whole period, the monthly ECG service utilization rates were around 90%. This showed that the service was well accepted by practitioners and incorporated to the health system of the municipalities. Therefore, the telecardiology is nowadays a regular health service in the state, integrated into the healthcare system.

The service proved to be economically sound, promoting savings of 45M USD for an investment of 10.2M USD; an outstanding achievement for telehealth in Brazil (return of investment = 4.4 and benefit-cost ratio = 5.3).

The tele-elctrocardiography in the ambulances and the organization of the services in the north of the state are expected to decrease myocardial infarction mortality.

Conclusion

The telehealth model developed in Minas Gerais, Brazil, has produced good clinical and economical results. As a consequence, it is now a regular health service in the State, covering 722 of the 853 municipalities and integrated into the healthcare system. The model and technology characteristics permit replication in other parts of the world.

Care Professionals' Perceived Usefulness Of A Rehabilitation Ehealth Service In Stroke Care

Nadia Davoody[a], Maria Hägglund[a]

[a] *Health Informatics Centre, Department of Learning, Informatics, Management and Ethics, Karolinska Institutet, Sweden*

Abstract

Despite many attempts to support stroke patients, there is still room for improvement. The aim of this study is to gain insight into care professionals' perceived usefulness of an online care and rehabilitation planning tool. A functional prototype was developed and presented to a neurology team in a primary care centre in Stockholm. Three focus group meetings were conducted. The data were analysed based on the unified theory of acceptance and use of technology. The results indicate that the care professionals were positive towards the tool and described potential usefulness such as ease of understanding the rehabilitation process and support for collaboration among care providers and also cooperation between the patient and the team. They also identified challenges such as time limitation in daily care.

Keywords:
Stroke; eHealth; Rehabilitation; Unified Theory of Acceptance and Use of Technology.

Introduction

Stroke rehabilitation is a cyclical process of identifying patients' problems, defining goals and activities and assessing patients' progress towards the agreed goals [1]. Post-discharge stroke patients in Stockholm County Council receive home-based rehabilitation from neurology teams up to one year. The teams establish a paper-based rehabilitation plan together with patients and possibly their next-of-kin. We designed a web-based prototype which provides a care and rehabilitation plan that includes *problems, goals, activities,* and *outcomes.* Other features are a *calendar, reminders, list of disabilities, care providers, assistive tools* etc. Patients can identify problems, set goals, and plan activities together with the neurology team or independently. As using the tool will affect the care professionals' work routines and job performance, we in this study explore their perceived usefulness of the prototype.

Materials and Methods

Three focus group meetings with members of a neuro team (speech therapist, occupational therapist, counsellor, and physiotherapist) were performed. A short description of the study was given in the beginning of each meeting, and the prototype was introduced. Each focus group meeting lasted about one hour. The meetings were audio recorded, transcribed verbatim and analysed deductively based on the Unified Theory of Acceptance and Use of Technology (UTAUT) [2] as it has been reported to explain 70% of the variance in intention to use information technology.

Results

The participants believed that the tool would be useful in their work and it would support the cooperation between the patient and the team; however, they believed that they would not be able to use it themselves due to time limitation (**Performance expectancy**). "I just think that we all are working MI [motivational interviewing] based today and this [the tool] gives the patient control of his/her own rehabilitation and we have the opportunity to work even more on MI…" (*Occupational therapist*) "If we want to work with this, there will not be much time over for training, so we will get stuck with it and with the computer." (*Physio therapist*)

Participants mentioned that the connection between problems, goals and activities would lead to a better understanding of the rehabilitation process (**Effort expectancy**) "It is good to connect them, then you understand why you do the exercises. It can sometimes affect the motivation." (*Speech therapist*) Participants also believed that the information content in the tool is imperative for patients to understand their journey.

Social influence was not identified as an important factor in this study.

Participants wished the program was available through mobile devices and integrated with the patient record system (**Facilitating conditions**). "Mobile applications would be great. It is something that the patient always has with him/her…" (*Occupational therapist*). Another important facilitating condition was the availability of technical support, both for healthcare professionals and for patients.

Conclusion

The care professionals were cautiously positive towards the tool stressing their limited time with the patients. Their acceptance was mainly dependent on the usefulness of the tool for team work and relationship between care professionals and the patient. Technical support played an important role in their decision about the acceptance of the tool.

Routine Health Information Systems in South Africa - Opportunities for Improvement

Edward Nicol[a,b], Lyn A. Hanmer[a]

[a] *Burden of Disease Research Unit, South African Medical Research Council, South Africa*
[b] *Division of Community Health, Stellenbosch University, South Africa*

Abstract

A recurring theme in published studies is the need for the appropriate human and other resources to support routine health information system (RHIS) implementation. While training in the use of specific RHIS and the availability of the required resources for implementation are essential for all users, other factors such as managers' understanding of the role of RHIS in supporting health services; the ability to interpret RHIS data; and a focus on data quality are further requirements for effective RHIS implementation.

Keywords:
Data quality, Routine health information system (RHIS), Health information system (HIS), Human resources, Competence, Health system strengthening

Introduction

Two reviews of progress made towards strengthening South African health information systems (HIS) in the context of current health sector policy initiatives identified multiple challenges which have persisted over the years due to factors including managers' inability to translate key health regulations and policies into practice; inadequate human resources; insufficient capacity of health information personnel; inadequate training; lack of resources such as registers, computers, and printers; limited HIS development planning; and lack of established HIS career paths and accredited training programmes[1][2].

Methods

Four studies on the evaluation of South African HIS by staff of the South African Medical Research Council published between 2010 and 2013 [3-6] were reviewed and the results synthesised to identify opportunities for strengthening existing RHIS performance and for improving future RHIS implementations. The foci of the respective studies were the effective use of computerised hospital information systems (CHIS) [4], RHIS resources [3], data quality challenges [5], and factors affecting data quality, such as RHIS competence and knowledge of RHIS rationale [6].

Results

The following key recommendations are made, based on the results of the review:

- Continue and strengthen efforts to ensure the effective use of existing RHIS, including the District health information system (DHIS) and other RHIS in use at patient, facility, district and provincial level.
- Strengthen management commitment and support, including appropriate resource allocation for RHIS [3][4].
- Focus on data quality, including allocation of required personnel and other resources to enable active monitoring of RHIS use and RHIS reports [4][5][6].
- Allocate, train and support management and end users in the use of RHIS. Multiple approaches and content are required. Include interpretation and analysis of data from the RHIS in management training [4][6].

Conclusion

This review has documented challenges of RHIS implementation in South Africa, and has identified opportunities for improving effectiveness of existing and future implementations.

Acknowledgments

The study was supported by the South African Medical Research Council.

Perceived Reasons for High and Low Quality Observational HIV Research Data

Stephany N. Duda[a], Catherine C. McGowan[b], Cynthia S. Gadd[a]

[a] *Department of Biomedical Informatics, Vanderbilt University School of Medicine, Nashville, TN, USA*
[b] *Department of Medicine, Division of Infectious Diseases, Vanderbilt University School of Medicine, Nashville, TN, USA*

Abstract

Audits of data quality in a Latin America HIV research network revealed that study sites collected weight measurements, laboratory results, and medication data of inconsistent quality. We surveyed site personnel about perceived drivers of their high or low quality data. Most sites reported their research teams contained no data specialists and that missing data stemmed primarily from incomplete patient assessments at the point of care rather than inconsistent data recording. The root causes of data errors resulted from limited clinic resources (e.g., broken scales, limited record storage space), workflow complications, or the indifference of external participants towards research activities. Understanding these factors supports targeted quality improvement processes.

Keywords:

Data Collection, Error Sources, Data Quality

Introduction

The Caribbean, Central, and South America Network for HIV research (CCASAnet), a network of HIV clinics in Latin America, conducts on-site reviews of routine clinical care data submitted for research by study sites. During a data audit, data coordinating center personnel check data submitted for research against the contents of paper clinical records (source documents), flagging data mismatches, missing data, and data with no documented origin. This source document verification helps quantify data quality to ensure meaningful research findings [1]. The audits revealed many discrepancies in CCASAnet sites' data. We investigated the causes of data quality differences across sites through a data quality survey.

Materials and Methods

We developed a survey that asked site personnel about the presumed causes of their high or low quality data. We focused on 3 high-error categories: weights, lab values, and medication history. The survey was approved by the Vanderbilt IRB, implemented in REDCap (projectredcap.org), and distributed by coordinators at each site. Survey responses were grouped by site, but anonymous within sites. The project ran March-June 2009. Two researchers independently selected recurrent themes through iterative, bottom-up analysis. Conclusions were harmonized through group discussion. A third researcher was appointed to resolve any conflicting interpretations.

Results

We received 18 survey responses, representing 6/7 CCASAnet sites. Respondents reported that clinicians conducted data abstraction rather than data personnel, and teams included on average 3-5 people. Reported reasons for missing *weight data* included broken scales and providers' perception that weight measurements were unimportant for clinical care. Two sites with high quality weight data described reducing missingness via multiple data capture opportunities

Auditors often could not find source documentation for th*e laboratory data* sent for research. Survey responses described oversized laboratory printouts that didn't fit into medical record folders, a lack of shelf space in the record room, and the practice of giving lab reports to patients as reasons for missing paper documents. The one site with high quality lab data received direct data exports from the laboratory system.

Sites with low quality *medication data* agreed that brief drug regimens were easily overlooked during data abstraction and delays between when a physician prescribes treatment, the government approves the treatment, and the pharmacy dispenses the drugs resulted in multiple, conflicting dates recorded in the patient chart. Collaborative work with local clinic pharmacies was reported as a reason for higher quality data, and sites benefitted from having access to pharmacy records as a secondary source of information.

Discussion

The responses of survey participants revealed that higher quality research data was the result of complementary processes (e.g., parallel laboratory or pharmacy workflow) or automated data imports, which reflects well-documented quality improvements when reducing manual transcription [2]. Most on-site data preparation roles were filled by clinicians although trained data clerks may conduct accurate and more cost-effective abstraction of basic data [3]. Respondent feedback informed potential approaches to reduce errors in HIV research data abstracted from patient care records.

Acknowledgments

The authors thank Daniel R. Masys, MD, and the teams at the CCASAnet sites. This work was supported by NIH/NIAID U01AI069923 and NCATS UL1TR000445.

Telehealth in Brazil: Contemporary Tool for Access to Health

Thais Vieira Esteves[a] and Sérgio Pacheco de Oliveira[a]

[a] *National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil.*

Abstract

This work raises questions about telehealth in Brazil, especially the areas of diagnosis, treatment and monitoring at distance, emphasizing its importance for the improvement of health conditions. It was based on a literature review. Three successful experiences were selected as examples: The Minas Gerais Project Telecardio, the São Paulo University Teleaudiology and Telerehabilitiation of UnB. Despite the increase of telehealth experiences in Brazil, much remains to be done in regard to diagnosis, treatment and follow-up, with potential positive effects on health.

Keywords:
Telehealth; Diagnosis; Treatment ; Monitoring.

Introduction

Internet technology has produced impacts on society and therefore, in health. The telehealth field, where communication for healthcare technologies is incorporated, is an important example for our country, due its geographical size and inequalities of distribution of health care resources. This study is a literature review that aims to show the level of development of telehealth in Brazil, focusing on experiences related to diagnosis, treatment and monitoring.

Materials and Methods

A literature search was conducted using the PubMed, SciELO and Scopus databases. The search terms were "internet" and "health," using the free form, selected for all levels, from 2010 to 2014. We found more than 200 articles and by reading the titles, we selected 73 texts for a full-content review. We observed just a few experiences in diagnosis, treatment and follow-up in Brazil. We selected three successful experiences to demonstrate the advances and challenges in the area.

Results

In the late 80s, telehealth began in Brazil, mainly at universities and research centers, increasing access to health care for residents of remote areas and reducing inequalities of health services. In 2010, the Ministry of Health created the Telehealth Program Brazil, which was redefined and expanded in 2011 with the goal of supporting the consolidation of the Health Care Networks in SUS. Although we have in Brazil, just a few experiences of diagnosis, treatment and follow-up, this paper selected three successful experiences as examples of improvement to the Brazilian heath system.

The Telecardio Project implemented a low cost telecardiology system in the small cities of Minas Gerais state. This enabled diagnosis in cardiology support for primary care physicians and improved referrals of complex cases, in addition to assisting the permanent education of municipalities' professionals. Today it is a permanent government program in the state of Minas Gerais.

The experience in Teleaudiology from São Paulo University was characterized by adapting individual hearing aids at distance. It was observed that in addition to adaptation, it allowed the training and preparation of professionals from a remote center using a specific hearing amplification software.

The Brasilia's University Telerehabilitation investigated the use of Internet for people with spinal cord injury. It proposed the improvement of care in rehabilitation services routines using the Internet as a tool for the well-being of patients.

Conclusion

Despite the growth of telehealth practices in Brazil, a lot still needs to be done. Telehealth is an important tool to support health actions, facilitating access to early diagnosis and decreasing the time to start of treatment, so the prognosis of the disease tends to be improved and the health cost decreased. On the other hand, Brazilian telehealth requires more infrastructure investment and stimulus as shown by the success cases, for early diagnosis, treatment and follow-up at a distance.

Stigma and On-line Health Information Seeking of U.S. South Asian Cancer Survivors

Sheba M. George, PhD [a, b] and Marjorie Kagawa Singer, PhD, MA, MN, RN, FAAN [a, c]

[a] Department of Community Health Sciences, UCLA Fielding School of Public Health; [b] Center for Biomedical Informatics, Charles R. Drew University of Medicine and Science, Los Angeles, CA.; [c] UCLA Asian American Studies Center, Los Angeles, CA.

Abstract

The internet has replaced physicians as primary health information source for cancer-survivors.It is important to uncover barriers/facilitators to cancer information seeking, particularly on-line.Asian Americans are the fastest growing U.S racial/ethnic minority, 2) cancer is the leading cause of r death and 3) cancer knowledge is low among them and little research is done on their cancer information seeking strategies. This study aims to examine qualitatively cancer information-seeking patterns of the Asian American group, South Asians, using in-depth interview methods. Family members and social networks are highly engaged in providing informational support to South Asian cancer survivors. such collaborative information seeking is limited by stigma related to cancer and must be taken into consideration when developing culturally appropriate cancer health information seeking interventions in such communities.

Keywords:

Health information seeking; cancer survivors; Asian American

Introduction

As cancer survivorship has become acknowledged as an important stage in the cancer continuum of care, health information seeking by cancer survivors is a major under-addressed area of need. The widespread access to readily available on-line health information has been characterized as having the potential to level the playing field for all patients, particularly for underserved racial and ethnic minority populations experiencing health disparities. Yet, Asian American survivors and familiesreceive limited guidance on health information seeking.[1]

Materials and Methods

A 90-minutes to 2 hours in- in-depth interviews were conducted with a sample of 40 participants, including 20 dyads of 20 cancer survivors, varying by level of education and 20 information-support providing family members/friends. South Asians included those having ethnic origins in the Indian subcontinent, including India, Pakistan, Bangladesh and Sri Lanka. Questions addressed a range of domains including expectations, experiences and needs that shape cancer health information seeking.

Results

Family members and social networks are highly engaged in providing informational support to South Asian cancer survivors, as is the case for other ethnic and minority populations.[2] In South Asian communities, differences in norms about patient autonomy and cultural/family values, linguistic challenges and health literacy may result in greater reliance of cancer patients on family members and social networks, such that they function as a unit, and in some cases, family members may conduct all information seeking for the cancer survivors. Such family-based information seeking behavior and patterns of communication go against assumptions about patient autonomy in the U.S. health care.

We found that their collaborative information seeking was limited by stigma or negative reactions to cancer in the community, which led to selective sharing of cancer with family and community. Participants characterized cancer stigma as: 1) judgment from God; 2) a marker of hereditary genetic failing and 3) a marker of lost social status, such as mastectomies, where women can be seen as not fully women.

Conclusions

To better understand health information seeking of Asian Americans, particularly recent immigrants, models of culturally collaborative or surrogate information seeking are needed compared to existing models assuming autonomous individual information seeking. For many South Asian cancer survivors, the fabric of life is intertwined with that of family/friends due to cultural, logistical, and linguistic dependency. Such a conceptualization would allow interventions to adapt health information resources/channels to relevantly meet the needs of these sub-populations. The explicit stigma against cancer points to the value of understanding the sources of such stigma, its impact on cancer health information seeking and developing appropriate strategies to deliver cancer information resources to such populations, particularly those with language/health literacy deficits.

End-User Experiences and Expectations Regarding Data Registration and Reuse Before the Implementation of a (New) Electronic Health Record: A Case Study in Two University Hospitals

Erik Joukes[a], Nicolette de Keizer[a], Ameen Abu-Hanna[a], Martine de Bruijne[b], Ronald Cornet[a,c]

[a] *Department of Medical Informatics, Academic Medical Center, University of Amsterdam, the Netherlands*
[b] *Department of Public and Occupational Health, EMGO+ Institute for Health and Care Research, VU University Medical Centre, Amsterdam, the Netherlands*
[c] *Department of Biomedical Engineering, Linköping University, Sweden*

Abstract

Patient data stored in Electronic Health Records (EHRs) are used during care provision but are also potentially usefully reused for other purposes. Data (re)use requires good data quality, which necessitates efforts by healthcare professionals for proper data registration. However, their commitment depends on their perception of the reuse benefits. We developed a questionnaire to investigate the perception and expectations of end-users on data registration and reuse in two university hospitals starting a joint EHR implementation. Especially personnel in direct patient care reports to spend much time (40%) on data registration and this group is not willing to spend more time with the new EHR. Additionally, approximately one third of the personnel did not yet have a clear view on future developments regarding data registration and reuse. We found only small differences between hospitals.

Keywords:
Medical Record Systems; Health Personnel; Data Registration; Electronic Health Records; Implementation; Data Reuse.

Introduction

Reuse of patient data stored in an Electronic Health Record (EHR) relies on data of sufficient quality and structure. The quality is influenced by the EHR and the personnel's attitude towards the importance and benefits of data registration but also the amount of time spent on registration. The implementation of a new EHR offers an opportunity to improve data quality. We investigated 1) how much time the personnel thought to spend on registering data now and how much they were willing to invest when working with a new EHR, and whether this differs between a hospital currently working with a legacy EHR versus one currently registering on paper, 2) how much faith the personnel has in the (future) registration and reuse of patient data.

Methods

Based on focus groups and a literature search, we developed an online questionnaire to measure the expectations of the (future) EHR end-users on data registration and reuse before the implementation of a new EHR. We invited for the questionnaire approximately 10,000 (future) EHR end-users of two university hospitals in the Netherlands (one with a legacy EHR, the other registering on paper) currently in the process of jointly implementing a new EHR. The majority of the personnel was not familiar with the functionality and effects of the new EHR.

Results

Of our target population 2,960 (30%) people responded. In general participants in both hospitals were satisfied with their work (mean 7.3-7.8 out of 10 maximum points), but satisfaction with the registration process scored lower (mean 5.1-6.5). The groups least satisfied with data registration were physicians, nurses, and scientific researchers (scoring < 5.5). There was no significant difference between the two hospitals in both work and registration satisfaction.

The most time spent on data registration was reported by nurses (40.2%), administrative staff (38.3%), and physicians (37.1%) the lowest was the group of facilitating staff (16.8%). We found that researchers, and analytical, facilitating, administration and support staff were willing to spend more time on registration for the sake of data reuse. Physicians and nurses wanted to spend 6.1% less time on registration with the new EHR, even when it is beneficial for reuse. In general 8.8% of the personnel (17% among specialists) expected the registration time to increase with the new EHR. About 38% do not have a clear view on future developments regarding data registration and reuse. In particular, they had no clear view on possible benefits of the EHR.

Conclusion

We found no statistically significant differences between health personnel currently working with a legacy EHR versus a patient record on paper. Nurses and medical specialists indicated they want to spend less time on data registration, even when it might save them time reusing the patient data. The majority of the participants was not satisfied with the current data registration process. Over one third of the participants did not have a clear view of what the new EHR will bring regarding data registration and reuse.

Quality of Life Measurements in Spinal Cord Injury Patients

Enea Parimbelli[a], Gabriella Fizzotti[b], Caterina Pistarini[b], Carla Rognoni[c], Silvana Quaglini[a]

[a] *Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Italy*
[b] *IRCCS Salvatore Maugeri Foundation-FSM, Pavia, Italy*
[c] *CERGAS, Bocconi University, Milan, Italy*

Abstract

We recently developed UceWeb, an application for direct elicitation of utility coefficients (UCs), i.e. a measure of health states quality perceived by patients. UceWeb was used to interview a sample of patients affected by spinal cord injury (SCI). A standard questionnaire for measuring quality of life (QoL) and another one for the system evaluation were also administered to the same patients. The aims of this work are to (i) evaluate UceWeb usability; (ii) investigate relationships among QoL values elicited with different methods, (iii) create a reference set of UCs for the health states experienced by SCI patients. We show preliminary results obtained with the first 20 patients. Despite great variability found among QoL values elicited with the different methods, interesting correlations with patients' condition and profile have been found.

Keywords:

Quality of life, Utility Theory, Spinal Cord Injuries

Introduction

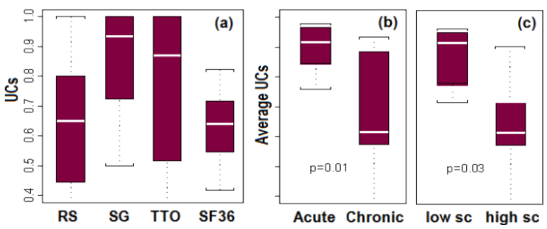
Measuring Quality of Live (QoL) of patients and correlating it with their clinical conditions may help to personalize treatments. Besides the individual level, specific QoL measures, namely the "utility coefficients" (UCs), are essential in cost-utility analysis, a technique used to evaluate interventions at a population level. UceWeb can be used by any physician, during face-to-face visits, to elicit UCs with the *classical* direct methods, i.e. rating scale (RS), time-trade-off (TTO), and standard gamble (SG) [1]. For each elicitation, a patient's (anonymous) profile is stored, so that, as the repository grows, it will be possible to retrive UCs for target populations. Moreover, relationships among UCs elicited with different methods could be studied, which also is a research issue. In this poster, we illustrate our first application of UceWeb, related to patients with SCI; an insult to spinal cord usually causing permanent and often devastating neurologic deficits and disability. With SCI, the ultimate goal of rehabilitation is to enhance QoL.

Materials and Methods

Twenty patients were consecutively recruited at the FSM Spinal Unit from October to December 2014. They were classified by the American Spinal Injury Association (ASIA) scale [2], from A (greatest impairment) to E (normal state). Using UceWeb, patients were firstly asked to rate their health state on a 0-100 scale (RS). Then they were asked to consider hypothetical scenarios: whether or not, and at which extent, they would give up part of their lifetime but living healthy (TTO); and which risk they would take, e.g. for a surgery, in order to be cured (SG). UCs were then calculated through known formulas. In addition, they answered the SF36 questionnaire, from which UCs were calculated using Brazier formula. A further Likert scaled questionnaire for evaluating the interaction with UceWeb was administered.

Results

Figure 1 – Some statistics on the elicited utility coefficients.



Boxplots show median and interquarile range (sc=scalarity)

All but 2 patients were very collaborative. Patients seem to understand RS and TTO methods slightly better than SG, for which two patients were not able to answer. While showing high variability, all scales are significantly correlated. According to past literature, RS values are significanly lower ($p<0.01$) than TTO and SG, both of which incorporate the concept of risk in their definition (Fig.1a). RS and SF36 values are similar. Chronic phase implies lower UCs than acute (Fig.1b), probably due to burden of reintegration in daily life. Low scalarity patients had higher UCs (Fig.1c). Moreover, even without statistical significance (probably due to small sample size), ASIA C patients have higher UCs than A and B, and paraplegic patients have higher values than tetraplegic.

Conclusion

UceWeb is a usable application for collecting UCs in a homogeneous way. Results obtained in SCI can be the basis for further reasoning on the effect of SCI on the quality of life.

A Methodology for Adapting Psychoeducational Content to Mobile Platforms

Stephanie Tucker[a], Sriram Iyengar[a], Amy Franklin[a]

[a] *School of Biomedical Informatics, University of Texas Health Science Center at Houston*

Abstract

Studies show that current modes of psychoeducation (PE) cannot be availed of by a substantial population of those in need. Mobile health technologies have great potential to serve such populations. However converting PE to mobile platforms is challenging. We present a methodology for this purpose based on existing learning styles theory, and developed PE apps successfully, using it. Conclusion: Useful PE apps can be developed easily using the proposed method.

Keywords:

Psychoeducation; apps; smart mobiles; rich media.

Introduction

Mental disorders affect 26.2% of American adults [1]. Although Cognitive Behavior Therapy (CBT) and Psychoeducation (PE) are effective, these are under-utilized because social (stigma), financial, and time constraints prevent many from accessing these therapies [2].

Mobile health (mHealth) technologies on smart mobiles (phones/tablets) offer great potential for overcoming these barriers. PE content on widely available smart mobiles can decrease the need for specially trained therapists. Cost of PE apps is typically less than one-on-one CBT and PE courses. Interactions with apps can be done privately, alleviating social anxieties in face-to-face settings.

However, effective adaptation of psycheoeducational content to smart mobiles is a challenging informatics problem. Existing PE content cannot simply be copied into mobiles. Greatest benefits can be achieved only by transducing content in ways that enhance usability, learning, and take full advantage of the powerful capabilities of smart mobiles.

We present a methodology, based on the Felder-Silverman Learning Style Theory [3], and prior experience with clincal practice guidelines on mobile platforms [4] to adapt PE content to smart mobiles. The methodology is generalizable to various kinds of PE content.

Methods

Adaptation of Felder-Silverman Learning Styles theory to mobiles yielded requirements that the PE content should be Active (quizzes, data intake, communicative), Reflective (self-paced), Sensing (interactive touch screens), Intuitive, Step-by-step, and have rich media (text, audio, images, video). To achieve these requirements, we converted PE content into an information flow model. We enabled sensing through touchscreens; interactivity by providing input modes such as sliders, application initiated photo and video taking. Rich media were built into every screen of the app, appealing to verbal and visual styles of learning. The typical large volume of PE content was broken up into smaller lessons in sequential order based on major content categories. In effect, the PE content was converted into a media rich patient-oriented Clinical Practice Guideline (CPG). Such guidelines on smart mobiles have high user acceptability and effectiveness in enabling adherence to guidelines [4]. Informatics challenges encountered include managing complexity of PE content, ensuring usability and navigational simplicity, choices of colors, fonts, text sizes, etc. App development was done, without programming, using the guideVue® system.

Results

Several PE apps were developed using the above methodology such as “road map to peace of mind” to provide PE to homeless veterans with mental disorders.

Conclusions

A broad, well-defined methodology is proposed to transduce face-to-face and paper-based PE to smart mobiles. It generalizes to any PE content that can follow a CPG format.

Disclaimer: The second author is part owner of a company aiming to comercialize the guideVue® system.

Special People in Routine Health Information Systems Implementation in South Africa

Lyn A Hanmer[a], Edward Nicol[a]

[a] *Burden of Disease Research Unit, South African Medical Research Council, South Africa*

Abstract

An analysis of roles and decision making structures to facilitate routine health information system (RHIS) implementation and use in public health facilities in South Africa identified a wide range of stakeholders in these processes. Two broad categories of RHIS 'special people' are analysed, i.e. leaders (administrative and/or clinical) and bridgers/support staff. In addition to health system personnel with specific responsibility for RHIS, users with an interest in effective use of RHIS and RHIS outputs, and staff of external system and/or service providers, can play significant roles in RHIS implementation and use.

Keywords:

Routine health information systems (RHIS); Health information systems (HIS); Health information system personnel; stakeholders; public sector; South Africa

Introduction

Ash *et al.* [1] have described in detail the roles of 'special people' who are essential to the success of computerised physician order entry (CPOE) systems. The focus of this analysis is the special people who contribute to the success of computerised routine health information systems (RHIS) in South Africa. The environments being considered include a wide range of public sector facilities, from primary health care (PHC) clinics to tertiary hospitals. In practice, the clinical and administrative leadership in many facilities, especially at PHC level, is provided by nurses.

Methods

The Ash *et al.* framework published in 2003 [1] identified three categories of special people: administrative leadership, clinical leadership, and bridgers/support staff. This framework has been adapted to reflect the situation for public sector RHIS in South Africa. The knowledge gained from detailed mixed-method studies of RHIS use in three of the nine South African provinces [2,3] was used to map the categories of special people identified in South African RHIS against the categories identified by Ash *et al.*.

Results

The revised framework for special people for RHIS in South Africa reflects an overlap between the personnel responsible in practice for administrative and clinical leadership, especially in primary health care settings, where the facility managers, who are responsible for administrative and clinical leadership, are likely to be nurses. Due to limited resources, including highly skilled resources to support the development, acquisition, implementation and use of RHIS, some of the roles in the Ash *et al.* framework are combined or do not exist in the RHIS environments studied.

There are multiple groups of people under the category 'bridgers/support staff'. Examples of identified RHIS special people indicate that there are additional categories of significance, including support people from outside the public health services (e.g. employed by health information system (HIS) suppliers, or by external service provider organisations to provide support to RHIS implementers). A different but important category of special people are those users with an interest in effective use of RHIS and RHIS outputs, who develop influential roles beyond those formally identified in their job descriptions, related to support for other users and/or in ensuring effective use of the RHIS in their environments.

Conclusions

These results highlight the multiple essential roles of people in management and at service delivery levels in contributing to successful RHIS implementations in South Africa.

Acknowledgments

The contributions of many special people to RHIS implementation in South Africa are gratefully acknowledged.

This study was supported by the South African Medical Research Council.

Emergency Department Information System Education and Training for Clinicians: Lessons Learned

Marcelo Lopetegui[a,b], Bernd Oberpaur[a], Macarena Vivent[a], Cecilia Carrasco[a], Alejandro Mauro[a]

[a] *Clínica Alemana de Santiago, Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Santiago, Chile.*
[b] *Department of Biomedical Informatics, The Ohio State University, Columbus, OH, USA*

Objective

Of all the potential barriers to a successful Electronic Health Record (EHR) adoption, the importance of training is often underestimated, potentially jeopardizing the implementation[1]. Following best practices recommendations, we designed and implemented a comprehensive EHR training framework. The aim of this poster is to describe our experience with such a framework in the implementation of our home-grown Emergency Department Information System (EDIS), report lessons learned and provide recommendations for other institutions facing EHR adoptions in Chile and Latin America.

Keywords:

Training; Emergency Department Information System; Education; Organizational Implementation.

Methods

Clínica Alemana de Santiago (CAS) is a 424 bed private hospital. The Emergency department (ED) receives 228,781 consults per year and has utilized a commercial EDIS since 2008. We designed and conducted the comprehensive training strategy in preparation for the deployment of a completely new home-grown EHR. We desigend a three-stage framework based on **education** (3 hours online course with teoretical material, short demo videos, and a test), **training** (45 min. 1-1 sessions where the clinician follows user stories, recording milestones completion and receiving directions if required) and **on-site support** (continuous 24/7 crew of technical and clinical experts serving as a personalised support and bug reporting system, for three months since the rollout).

Fourty five days prior to the rollout, we invited all the ED clinical staff to access the on-line education system using their institutional credentials, and once completed and approved, to schedule a training session either via e-mail, phone or walk-in (if available). Everybody was expected to complete the training before the rollout. After the rollout, reduced capacity training was still available for new hires.

Results

The described methodology provided the required preparation, contributing towards the success in the adoption of the new EDIS. We received positive feedback from unit administrators who perceived well prepared clinical staff for the implementation. Although the model was succesful, interesting lessons were learned, which will be addressed before the rollout of our new outpatient module of the EHR.

Discussion

Based on an extensive literature review and our experience implementing the framework, we have gained valuable experience including:

- Manage timing with the developer team: gain access to stable version in advance to prepare training material.
- Consider also enrolling residents in the training framework.
- Reduce size of theoretical written material and provide more short categorized videos.
- Online education needs to be differentiated: distinct courses with different coverages for distinct clinical entities.
- Demonstrate the value of your training to clinicians by showing how a well-organized chart helps to provide a safer and more efficient patient care, and the explain the relevance of good quality clinical data for secondary use.
- Deploy satellite training facilities in the users' regular resting spaces (i.e. physician's lounge).
- Provide enhanced training to key clinical stakeholders given that peer-to-peer training is usually preferred by clinicians.
- For newly hired clinicians, integrate the EHR training and education within the regular clinical service orientation classes, introducing the learner to the complete culture, processes and documentation methods of the organization.
- Avoid implementations during the summer: less crowded ED did not compensate for the amount of floating staff and the double training effort required when primary staff returned to work. Find a low demand period with primary staff available.
- Only provide access to EHR if education module is approved. However, be prepared to provide "emergency on-site training", for untrained healthcare providers showing up for their shifts withouht propper education and training
- Provide a distinctive uniform that differentiates your support staff from usual clinical staff, facilitating their location by clinicians, while preventing confused patients seeking help from them.
- Maintain a continuous streamlined feedback and bug reporting mechanism.

The Role of the IT Department in Information System and Organizational Redesign

Lone Stub Petersen[a]

[a] *Danish Center for Health Informatics (DaCHI), Department of Planning, Aalborg University*

Abstract

This paper is based on a qualitative study of IT organization and clinical practice over a period of 3 years supported by additional data during the last 2 years. This paper argues that redesign is central to understanding and developing both healthcare information systems and organizations. The importance of the IT organization is also stressed throughout this paper as a pertinent partner and power when considering organizational change and learning in hospitals as it can serve both as a barrier and a catalyst of change and flexibility in the organization through information systems management. Therefore it is important to consider and secure appropriate forms for redesign and learning in cooperation with the IT department.

Keywords:

Redesign, Health informatics, Information Systems Management, Organizational implementation, Organizational change.

Introduction

In order for the IT department to accommodate the needs of the hospitals there is a need for developing an understanding of the complex relationship between the IT department and clinical practice. In this paper the complex structures and the support organization in hospitals are described. Also, with the concept of redesign exemplified through the case study, I will show how IS management is an important player in the continuous change of organizations and work practices.

Methods

The main focus of the case is on different manifestations of support-work in the North Denmark Region. The data was gathered through qualitative fieldwork in the North Denmark Region including interviews, meetings and observations, supplemented by insight into a range of documents, reports and manuals. In all, 30 interviews, 12 days of observation and participation in 10 meetings and 4 workshops were conducted.

The study method was inspired by ethnomethodology and actor-network studies. Following the actors, the interviews were semi structured and explorative in nature in order to capture the differences in practice and conceptualization of support work in the different parts of the hospital.

Results

IS-Management and Ongoing Development

A central set of tasks of the IT department is called 'systems ownership' which in this paper is termed Information Systems (IS) management. IS management involves tasks and competencies related to IS support as well as systems development in the ongoing maintenance and redesign of the information systems. In this sense, IS management is an essential part of the ongoing development of systems and work practices in the hospitals.

The Work Tasks of IS-Management

The task of IS-management involves communication with user groups, vendors and other stakeholders of systems that interface with the system in question. No real model or framework is in place for this kind of work in the timeframe of the study. The numerous steps and tasks involved in managing information systems are analyzed with a focus on the themes: managing and prioritizing requests for changes and handling challenges of systems integration and dependencies.

Managing and Prioritizing Requests for Changes

The management of information systems in the hospitals involves making sure the systems are developed further in accordance with and to enable the work practices of the hospitals. This involves getting feedback from the organization on problems, errors, breakdowns and general requests for systems functionality. The importance of continuous development of information systems was apparent in many cases of the field study.

Systems Integration and Dependencies

The information systems in the hospital are not just singular and independent applications. They are integrated and dependent on other systems and technologies in many different ways in order to share data and make different systems interact in the work practices. For the CPOE at the North Denmark region, the following are integrations and dependencies:

- PAS (Patient administration system)
- The Danish Medicines Agency (lægemiddelstyrelsen)
- ApoVision – the hospital pharmacy system
- Digital bloodsugar transfer system
- The new EHR – ClinicalSuite
- New integration to the system MedOnc where cancer treatment can be shown in the CPOE
- The new shared medical card (FMK)

Conclusion

The continued redesign of organizational practices in the hospital and the need for redesigning both systems and work practices are highlighted in the case study. Hence securing appropriate and meaningful use of information technology and systems in the hospital is of key importance in order to provide quality care for patients, as these technologies are core

aspects of the hospital work practices. The input from both general and local levels are also important for the management of information systems, and the changes and development of information systems are only brought into use through good support and educating structures. Therefore the IT department plays an important, yet easily downplayed role in the redesign of the organization through the redesign of information systems.

Acknowledgments

I would like to thank the region of North Denmark for supporting the project as well as my colleagues Pernille Bertelsen and Christian Nøhr for critical comments.

Developing an Open-Source Bibliometric Ranking Website Using Google Scholar Citation Profiles for Researchers in the Field of Biomedical Informatics

Dean F. Sittig[a], Allison B. McCoy[b], Adam Wright[c], Jimmy Lin[d]

[a] *The University of Texas School of Biomedical Informatics at Houston, Houston, TX*
[b] *Department of Biostatistics and Bioinformatics, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA*
[c] *Division of General Internal Medicine, Brigham & Women's Hospital, Boston, MA*
[d] *College of Information Studies, University of Maryland, College Park, MD*

Abstract

We developed the Biomedical Informatics Researchers ranking website (rank.informatics-review.com) to overcome many of the limitations of previous scientific productivity ranking strategies. The website is composed of four key components that work together to create an automatically updating ranking website: (1) list of biomedical informatics researchers, (2) Google Scholar scraper, (3) display page, and (4) updater. The site has been useful to other groups in evaluating researchers, such as tenure and promotions committees in interpreting the various citation statistics reported by candidates. Creation of the Biomedical Informatics Researchers ranking website highlights the vast differences in scholarly productivity among members of the biomedical informatics research community.

Keywords:

Citation ranking; h-index; Bibliometrics.

Introduction

Since Eugene Garfield first created the Science Citation Index, researchers and research administrators have used citation concepts as a means of ranking the scholarly production of researchers. Over the years, numerous citation statistics have been developed in an attempt to identify measures that are highly correlated with research productivity and scientific impact regardless of: (a) scientific field, (b) length of time of the researcher in the field, (c) the influence of a few of the researcher's highly cited articles, or (d) other arbitrarily determined factors (e.g., number of articles with a specified number of citations or number of articles in journals with an impact factor $\geq$ x). We developed the Biomedical Informatics Researchers ranking website in an attempt to overcome many of the limitations of previous scientific productivity ranking strategies.

Background

With its Google Scholar website, Google has revolutionized the citation analysis comparison process by creating an online, freely available, automatically updating, scientific information resource. With the addition of the ability for researchers to create their own "my citations" page, complete with several bibliometric calculations (e.g., total citations, h-index, i-10 index), Google provides a potential method for researchers to compare themselves to other researchers.

Methods

This open-source application is written in Node.js® and built using commonly-available open source libraries. It takes as input the list of researchers and then iteratively retrieves the listing of each person's Google Scholar citation counts, the total number of citations, the year of first citation, the i10-index, and the h-index. These values are extracted based on matching the relevant elements from each page's DOM (Document Object Model) structure.

In addition to extracting raw statistics from profile pages, the application also calculates the citations/year, i-10 index/year, and h-index/year; all computed values are written into a file in JSON format, which faciliates the display as well as downstream processing by other applications.

Results

The Biomedical Informatics Researchers ranking website is available at: rank.informatics-review.com. From 16 May 2014 – 30 November 2014, 876 unique individuals accessed the site during 1,585 sessions (mean duration 1:29).

In an attempt to predict future highly cited researchers, we calculated the correlation coefficient between the h-index and total citations (r^2=0.8) and i10-index (r^2=0.93).

Conclusion

We have developed an easily searchable, interactive, automatically updating, open source, bibliometric ranking website using Google Scholar citation profiles that includes over 600 Biomedical Informatics researchers from around the world. While there are definite limitations to both using bibliometric citation analysis to measure scientific productivity, and to automatically generate lists of articles and citations, the Biomedical Informatics Researchers ranking website has already proven to be useful for a number of important tasks.

Abstract

In Europe, health and medical administrative data is increasingly accumulating on a national level. Looking further than re-use of this data on a national level, sharing health and medical administrative data would enable large-scale analyses and European-level public health projects. There is currently no research infrastructure for this type of sharing. The PHRIMA consortium proposes to realise the Public Health Research Infrastructure for Sharing of health and Medical Administrative data (PHRIMA) which will enable and facilitate the efficient and secure sharing of healthcare data.

Keywords:

Europe, data sharing, public health, research infrastructure.

Introduction and background

In Europe, data on the health of the population differs greatly in terms of availability, size and content. In Sweden and Denmark, national health databases are administered by one single authority and contain information on the entire population on diverse aspects of population health. In France, the SNIIRAM holds information for almost the entire population on health insurance beneficiaries consuming care, including reimbursed prescribed drugs. In the United Kingdom, the CPRD contains observational data from the NHS, notably primary care records for around five million patients. In Germany, the Information System Secondary Use of Routine Health Data has been newly initiated, is maintained by the DIMDI and contains administrative claims data.

Methods

Aspects of data sensitivity, heterogeneity, legal and ethical issues of sharing, quality and semantic interoperability, as well as technological solutions to ensure security, need to be considered with new concepts and rigor as to enable sharing of health data on a European level. Interoperability challenges necessitate existing solutions to require European level efforts to harmonize and ensure data sharing, given data security and ownership. ESFRI [1] is a strategic instrument to develop interoperable platforms and research infrastructures (RIs). In Sept 2014 the authors began PHRIMA, a consortium to investigate a RI for sharing medical administrative data. This RI will specifically target national databases, extendable to patient and population cohorts.

Expected benefits

PHRIMA will strengthen technological development capacity and effectiveness through metadata definitions and semantic interoperability. It strives to harmonize European medical and administrative data, and propose technical solutions for data sharing; building on national solutions and other data shareable, reusable ESFRI projects. It supports collaborative research in record linkage and anonymization. The RI will provide secure, legal solutions for large-scale epidemiological research on observational health data.

Towards a Tool for Malaria Supply Chain Management Improvement in Rural Ghana

Lorena Carlo[a], Suzanne Bakken[a], Lena Mamykina[a], Richmond Kodie[b], Andrew S. Kanter[a]

[a] *Department of Biomedical Informatics, Columbia University*
[b] *Millennium Villages Project, Bonsaaso, Ghana*

Abstract

The maintenance of adequate quantities of antimalarial medicines and rapid diagnostic tests (RDTs) at health facilities in rural areas of sub-Saharan Africa is a challenging task because of poor supply chain management. Antimalarial stock-outs in the communities could lead patients (that need to travel long distances to get medications) to remain untreated, develop severe malaria and die. A prototype to improve the management of health commodities in rural Ghana through the visualization of current stock levels and the forecasting of commodities is proposed.

Keywords:

Malaria disease; mHealth for logistics; User centered design; Low and Middle Income Countries; Ghana.

Introduction

Malaria is a disease transmitted by the bites of infected mosquitoes. Every 30 seconds a child dies of malaria in sub-Saharan Africa [1]. There is a need for reliable healthcare data at all levels of provision. The access to timely, complete and accurate data could improve decision-making and healthcare delivery at the point of care and improve patients' outcomes [2]. Maintenance of adequate amounts of health commodities at the point of care in remote rural areas is a major barrier to the successful management of diseases in resource-poor settings. Effective information systems in health commodity supply chains are necessary to address this challenge.

Methods

The theoretical underpinning for this research work is the Sittig and Singh 8-dimension socio-technical model, which has been used to improve health information systems in different settings and stages [3]. A User-Centered Design approach was used to design a prototype to improve the management of malaria health commodities in rural Ghana. This involved focus groups, observations, interviews, and participatory design sessions. Qualitative data were analyzed using content analysis methods. Two focus group sessions were conducted. One with health workers (n=12) to collaboratively create supply chain process workflows, and one with the managers (n=6) to validate/correct workflows developed by the health workers focus group. Challenges and opportunities in the supply chain process were investigated in the focus groups as well. Observations and interviews were performed to verify the findings from the health workers' and managers' focus groups. Informants included 14 Community Health Workers (CHWs), 6 Community Health Nurses (CHNs), 3 midwives, 2 enrolled nurses, the supply chain manager, the malaria focal person, the CHW manager, the health coordinator and the eHealth specialist. A participatory design study was performed to identify and refine requirements. Using 24 participants, 14 participatory design sessions were held. CHNs and CHWs were grouped together because they interact closely in their work and have the potential to produce a richer set of requirements in a shorter period of time. A low fidelity prototype was created and evaluated with 5 CHWs, 4 CHNs, 4 midwives, 4 enrolled nurses and 3 managers, with the objective of refining requirements and obtaining feedback on the user interface.

Results and Discussion

Three primary themes emerged from the focus groups that identify the following challenges in the malaria health commodities supply chain management process: (1) malaria health commodities shortages; (2) delays in distribution of commodities; and, (3) difficulty managing manual inventory of commodities. First, there have been shortages of malaria health commodities at MVP Ghana cluster clinics. Further, it has been reported that the CHWs have run out of malaria commodities at the communities. Second, delays in the distribution of the commodities create scenarios where the CHWs borrow medication from their peers. Similar problems occur between clinics when they are unable to obtain the commodities on time. Data quality errors were reported in the collection of the inventory of commodities. The following key activities of the malaria health commodities supply chain process were observed and documented using workflows: malaria health commodities stock levels; forecasting of malaria health commodities; order of malaria health commodities; and dispensing of malaria health commodities. Future work includes evaluation of the prototype with experts and with the end-users.

Abstract

Interoperability of health information systems is a centerpiece of the "E-Health" Brazilian Ministry of Health strategy. It aims to solve at least partially the health information technology puzzle that we face today. This paper describes a health information exchange pilot project in a health district of the city of São Paulo. It discusses the results of the development of an informed consent form for health information exchange. This consent form showed excellent results, with median application time of 3 minutes and with 97.8% of patients feeling fully clarified. The patients' perception when faced with options of consent to share their data is also described.

Keywords:

Medical Informatics; Health Information Exchange; Informed Consent.

Introduction

Health information Exchange (HIE) has been proposed by health care leaders as an essential tool to improve the quality and cost-effectiveness of health care, improve management of public health data and obtaining information and assist in early detection of disease outbreaks [1]. Without previous experience well described in Brazil, a consent form was developed in a pilot project in a health district of the city of São Paulo.

Materials and Methods

A consent form including applicable laws, types of consent, patients rights, consent revocation, minor patients autonomy, proxies and legal guardians, data audit and data correction was created. A draft of a consent form was elaborated. After review by a committee, the final version was released. It was submitted to patients of Mooca health district in São Paulo, between October and November 2014. We also elaborated questions to be answered by patients after the consent process to evaluate the process and the acceptability to share clinical data in an interoperable system.

Results

Recording of consent and the study on the consent process began in October 2014 and here reported is the initial experience with 1235 patients. The average time of application of consent was 3.31 minutes and the median was 3 minutes. The minimum time was one minute and the maximum was 10 minutes.

From the total, 97.8% reported receiving adequate prior information for the signature of consent. The type of consent granted is showed in table 1.

Table 1 – Types of consent

Type of consent	Number (%)
Do not consent to share	51 (4,1%)
Consent to share at any health encounter	1101 (89,2%)
Consent to share only in emergency situations	62 (5%)
Consent to share only to epidemiological control	21 (1,7%)

The most remembered risks were wrong data entered in the system, invasion of the system and information leakage.

Conclusions

Initially we were afraid that the patients would not consent. This project showed that this is not the case. Of the total initial sample of 1235 patients, 94.1% showed confidence in the system and chose to share clinical information. Our perception is that the time invested is highly rewarding and we suggest that the consent process is maintained on a large scale. Even in a relatively short period of time, 97.8% of participants felt that the process was complete and appropriate decisions were made in participating.

Healthcare in Disasters and the Role of RFID

Samaneh Madanian[a], David Parry[a] and Tony Norris[a,b]

[a]*School of Computer and Mathematical Sciences, Auckland University of Technology, Auckland, New Zealand*
[b]*University of Agder, Kristiansand, Norway*

Abstract

Disasters either natural or man-made are inevitable, and therefore disaster management has always been an important function of government. Since during a disaster healthcare is often adversely affected, a lot of effort has been made in terms of researching effective responses and ways of improving the quality of delivered care to direct casualties and the rest of the community. In this regard, information technology plays an important role to help healthcare systems achieve this goal. One of these technologies that has become popular recently is Radio-Frequency Identification (RFID). This paper explores the relationship between emergency management and disaster healthcare and examines the role of RFID. It is suggested that RFID will become an integral part of disaster healthcare and a means of improving response performance.

Keywords:
Healthcare; RFID technology; Patient Safety; Disaster Response

Introduction

No society can claim immunity to disasters, thus planned disaster management – including the four phases of mitigation, preparedness, response, recovery – is an essential requirement. If enacted properly, it can lessen the harmful effects of disasters to a great extent. During disasters, healthcare plays an important part in responding to the needs of disaster casualties. In the Haiti earthquake, for example, estimates showed that the number of immediate quake-related deaths was around 200,000 and the number of injured survivors was about 300,000.

Two crucial challenges in disasters are patient identification and medical history. During disasters, medical staff deals with casualties who are unconscious and unaccompanied, and with children without their parents, none of whom can explain their current medical situation and needs, or their previous history. Patients can also be transferred among field hospitals with little more than a short medical summary written on their casts.

Materials and Methods

RFID in Today's Health Environment

The primary goal of RFID in healthcare is the enhancement of patient safety by reducing errors in patient care, including adverse drug effects, allergies, patient–medication mismatches and medication dosage errors.

RFID can reduce the inherent human errors and consequent risk by automating the communication process and delivering relevant and accurate information to responsible organizations that can employ medical resources rapidly and efficiently.

RFID in Disaster Response

The considerations noted above apply to normal, non-disaster situations, but they are even more pertinent to catastrophes where reducing loss of life and rapid recovery in the immediate aftermath of a disaster are priorities.

These attributes mean that the use of RFID technology in disasters has recently attracted a lot of attention. Central to this interest are the three fundamental characteristics of RFID: identification (who is the patient?), location (where is the patient?), and status (what is the patient's condition?).

These characteristics are of paramount importance in emergencies, as there is a 72-hour "golden" rescue period following an earthquake during which the efficiency of emergency response procedures is key to the rescue operation. If accurate and real-time information is accessible during this period, disaster management teams can coordinate more effectively the operations led by local, regional, and national organizations, and, as a result, make faster and better joint decisions.

One of the most critical tasks during this 72-hour window is triage, which not only needs to be correct and rapid, but must be recorded and communicated accurately to the responding clinicians. An RFID tag, when attached securely to a disaster victim, readily supports these requirements. The information on the tag can also avoid delays caused by repeated requests for the same information as well as be transmitted to a hospital in advance of the patient's arrival to expedite treatment.

In addition, RFID tags can monitor evacuees and control the procurement and targeting of medical supplies in order to help save lives in major disasters like earthquakes. RFID can also integrate information flow automatically, promoting its visibility among disaster responders and coordinators in different organizations, and helping them to coordinate their responses.

The benefits noted above will only be realized if several current limitations of RFID are addressed. The constraints include implementation costs, the interoperability between competing RFID standards, scaling problems, and the dual hurdles of privacy and security. These concerns are as important as the technical issues, and future research must address them in combination to earn the confidence and trust of both practitioners and patients.

Measuring Population Health Using Electronic Health Records: Exploring Biases and Representativeness in a Community Health Information Exchange

Brian E. Dixon[a,b,c], P. Joseph Gibson[a,d], Karen Frederickson Comer[e], Marc Rosenman[b,f]

Abstract

Assessment is a core function of public health. Comprehensive clinical data may enhance community health assessment by providing up-to-date, representative data for use in public health programs and policies, especially when combined with community-level data relevant to social determinants. In this study we examine routinely collected and geospatially-enhanced EHR data to assess population health at various levels of geographic granularity available from a regional health information exchange. We present preliminary findings and discuss important biases in EHR data. Future work is needed to develop methods for correcting for those biases to support routine epidemiology work of public health.

Keywords:

Electronic Health Records; Health Information Exchange; Geographic Information Systems; Community Health Planning; Health Services Needs and Demand

Introduction

Public health authorities monitor population health to identify burden of disease, manage health assets, establish policy, and evaluate interventions. This assessment usually relies on a limited set of information available through surveys, vital records, and paper-based disease reporting. Electronic health record (EHR) systems may provide more timely data for a larger portion of a population. Yet there exist a number of challenges to routine use of EHR data, including linking them to community data about social determinants of health. In this study, we sought to develop and evaluate neighborhood-level indicators of population health using EHR data integrated with a community information system (CIS).

Methods

The Indiana Network for Patient Care (INPC), a large health information exchange with over 5 billion clinical observations from EHR systems, was geospatially enhanced and combined with social determinant data from SAVI, a community information system serving the same geographical region (1). We then assessed the prevalence of diseases of public health interest and calculated HEDIS-like clinical quality indicators. Using statistical methods we assessed the reliability and representativeness of these data to measure population health at various levels of geographic granularity

Results

Rates of diabetes ranged from 1.5% to 16.07% with an average of 8.9% among neighborhoods spread across a metropolitan area. When examined at the census tract level, diabetes rates ranged from 1.5% to 12.83% with an average of 8.9% of the population for a given area.

We identified three biases in using EHR data. First, EHR data only represent those that seek health care. Second, linked EHR data are biased based how patient records were matched. The HIE uses a probabilistic technique, which can result in duplicate records. Third, the HIE proportionally contains more data from low income providers. We are exploring ways to adjust rates and correct these biases so they do not overestimate burden of disease and poor care quality in inner-city neighborhoods. We seek to compare census tract, neighborhood, and other geographic area measures with data from a recent population survey.

Conclusion

EHR systems capture data about more people than do population surveys, but they have biases that affect their estimates of population health indicators such as disease prevalence or preventative screening rates. Future work is needed to develop methods for correcting for those biases to support routine epidemiology work of public health.

The Collaborative Coordination of Special Interest Groups on the Telemedicine University Network (RUTE) in Brazil

Thiago Delevidove de Lima Verde Brito[a], Roberto Silva Baptista[a], Paulo Roberto de Lima Lopes[b], Ana Estela Haddad[c], Luiz Ary Messina[b], Ivan Torres Pisa[a]

[a] *Graduate Program in Management and Health Informatics, Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil*
[b] *RUTE National Coordination, Rede Nacional de Ensino e Pesquisa (RNP), Brazil*
[c] *Odontology Faculty, Universidade de São Paulo (USP), São Paulo, Brazil*

Abstract

In Brazil the Telemedicine University Network (Rede Universitária de Telemedicina RUTE) is an initiative that among others promotes collaboration between university hospitals, universities, and health professionals through information technology infrastructure and special interest groups (SIGs) support. This paper presents results of analyses on collaboration during implementation and coordination activities of RUTE SIGs. This study is based on descriptive statistics and data visualization previously collected by RUTE national coordination relative to the status in July 2014. The analysis through collaboration graph identified the strongest collaboration RUTE units. The graph also highlights the collaborative relationship of RUTE units in form of communities, the most collaborative with each other in a communion in the same SIGs, and the less collaborative units in the network. It should be stated that the most active units are also the oldest in the community.

Keywords:

Telemedicine; Telehealth; eHealth; Hospitals; Teaching.

Introduction

One of the Telemedicine University Network (RUTE) [1] integration actions is to promote special interest groups (SIGs). In these groups, created and coordinated by RUTE members, institutions distributed in all Brazilian states and covering all university hospitals belonging to federal universities, health professionals plan an agenda of videoconferences and webconferences to discuss specific themes in different health specialties and subspecialties. This paper, presents results of collaboration analysis by implementing and coordinating SIG activities among the practices of telemedicine and telehealth on RUTE.

Methods

This study was developed based on previously collected data by RUTE national coordination, that also supported the production of the second RUTE book about its 100 first units launched and fully operational [1] in Brazil. During the period of data collection which lasted from April to July 2014, coordinators of the first 100 RUTE units and 60 SIGs were invited to answer an online survey about their current status. Based on these data, a process of data visualization in form of graphs to represent the social network analysis [2] on RUTE focusing on coordinating SIG units was carried out. Three main highlights were noted on the following graphs and discussed as relevant results.

Results

As shown in Figure 1, RUTE units (nodes) considered most collaborative are located in the center of the graph and are interconnected according to the SIGs coordination number. Those units are: UNIFESP, UERJ, UFBA, ISCMPA, UFSC, UFES, UFRN and HSL. Acronym: http://bit.ly/1Ozb5kK.

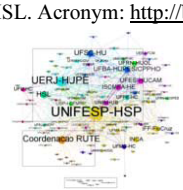

Figure 1– RUTE network graph based on SIG collaboration

The graph represents the collaborative relation of RUTE units in form of communities, where groups of nodes that have same color mean higher degree of relation and common participation in the same SIGs. Thus, we can note for example a community formed by National Coordination RUTE unit (Coordenacao RUTE). The graph represents also RUTE units with smaller collaboration degree: FioCruz-Canal Saúde, Amparo Maternal, UFPR, UFAC, HMOB, CHMSA, FMTAM, UFRJ-IG and FHAJ.

Conclusion

The analysis through collaboration graph identified the strongest collaboration RUTE units, the collaborative relation of RUTE units in form of communities, and units with lower collaboration degree.

A Novel Approach to Teach Medical Informatics

Jürgen Holm[*], Thomas Bürkle[*], Rolf Gasenzer, François von Kaenel, Stephan Nüssli, Serge Bignens, Sang Il Kim, Michael Lehmann

Institute for Medical Informatics, Bern University of Applied Sciences – Engineering and Information Technology, Bern, Switzerland [*]contributed equally

Abstract

The Bern University of Applied Sciences established the first Swiss Bachelor of Science in Medical Informatics. We demonstrate the specifics of the new curriculum that was based on requirements analysis and includes seminars and live case studies to enable problem-solving abilities.

Keywords:
Education; Medical Informatics.

Introduction

While other countries established academic medical informatics curricula for many years [1], Switzerland did not have such a program until recently. In 2009, a survey of requirements was conducted among 22 Swiss healthcare specialists (selected by quota from hospitals, healthcare IT companies, government, suppliers of medical equipment, service providers, consulting and health insurance). The survey provided the requirements needed for 700 medical informatics graduates during the next five years in Switzerland [2].

Methods

The survey results were used to set up a detailed score for the most and least needed study subjects in a five and ten year perspective. Interoperability, clinical pathways, and the Swiss national eHealth strategy ranked as the most popular subjects for the five year perspective whereas telemedicine and a national electronic health record dominated for the ten year lookout. Based on these results, a bachelor curriculum of 180 ECTS in 49 modules (three years full time or 4.5 years part time) was implemented in 2011 and comprised of explicitly the most desired study subjects in Biological Sciences modules such as clinical pathways or interoperability.

Results

The final curriculum splits in three core components: informatics (54 ECTS); healthcare and medicine (54 ECTS); and management and communications (58 ECTS) plus 14 ECTS for optional subjects. Module topics were carefully chosen considering the survey results. Informatics is covered with courses such as basic informatics, medical statistics, methods of programming, databases, software engineering and networking. Healthcare includes courses such as anatomy and physiology, medical documentation and pathology, and also includes interoperability, accounting in healthcare, clinical studies, clinical pathways, eHealth, and quality management in medicine.

Most interesting, however, the management and communications area has increased the number of courses, and together with the healthcare and informatics area, the two groups created a series of seminars, tutorials and exercises. In these seminars, students are guided towards the application of knowledge in practical exercises and self governed work. Students receive one or two publications around a medical informatics "hot topic" like big data in medicine or personalised medication. They perform their own research including organized visits to events such as the Swiss medical fair IFAS or the German conhIT, where they can talk to international experts. They are encouraged to search interview partners in the Swiss Medical and Informatics scene and must present their results in an oral presentation, a poster, a short paper and a detailed report. Thus the other experts profit from the student work. Live cases go beyond and result in clickable mockups or functional prototypes for a medical informatics application area (often together with industrial or hospital partners). Examples of live cases include an application to identify patients for radiation therapy using barcode scanners to enhance patient safety, or the design of a hospital portal for patient admission to radiology.

Conclusion

The first graduates finished in 2014 and received immediate employment. Although many recommendations on medical informatics education exist [3], they do not consider country specific requirements, e.g., local ehealth strategies or electronic patient dossier programs. Technology and healthcare changes mandate adaptation of educational curricula. Survey-based adjustment and teaching improved problem-solving abilities seem to be promising strategies in these circumstances.

Computer Experience of Nurses

Luciana Schleder Gonçalves[a], Talita Cândida Castro[b], Soraya Fialek[c]

[a] Nurse, Master in Health Informatics, PhD in Nursing, Professor at Federal University of Parana, Member of Research Group on Politics. Management and Health Practices GPPGPS-UFPR; [b] Nurse, Nursing Graduate Student at Federal University of Parana, Member of Research Group on Politics, Management and Health Practices GPPGPS-UFPR; [c] Nursing Undergraduate Student at Federal University of Parana, Member of Research Group on Politics, Management and Health Practices GPPGPS-UFPR

Abstract

This study aimed to identify the computing experience of nurses in southern Brazil, through exploratory survey research. The results, which were obtained from the application of The Staggers Nursing Computer Experience Questionnaire®, were analyzed by statistical tests. The survey was conducted with nurses working both in hospitals, as in public health, in a capital in southern Brazil. There is the predominance of novice nurses in the application of computer tools in their practices but most often declare the use the computers to develop their professional and also personal life activities. We conclude that the computer and health information systems are part of the working reality of the participants, being considered indispensable resources his activity, while noting limitations on the potential use of these tools. This study reflects on how the issue has been addressed in educational schools and the challenges of inclusion of the theme of Nursing Informatics in the curricula in Brazil.

Keywords:

Health Information Systems; Nursing Informatics; Nursing Informatics Competencies.

Introduction

The incorporation of new technologies has occurred steadily over the evolution of nursing, a fact that has enabled the expansion of the professionals' practice. It could have contributed to the improvement of the scope of their professional practice. Nurse's performance in different scenarios: caring, education, management, and research. Information and communication technologies (ICT) are support tools that can help health professionals achieve the efficient management of the high range of data produced in healthcare area (1). In 2013, the Center for Studies on Information and Communication Technologies (CETIC.br) promoted a large and pioneering study on the use of ICT in health facilities in Brazil, as well as appropriation of these technologies by industry professionals - the "Health ICT" research (2). In general, this research shows that professionals see as positive the implementation and use of information in health systems. They point out that the inclusion and use of these tools add value to the work process, thus contributing to gains in terms of efficiency and quality. It is believed, however, that the professionals are often placed in the context of ICT in the workplace, but without having received the necessary training to their best use. This can cause them to have little positive view of the tools as a means of facilitating their work (2).Based on these assumptions, this study aimed to identify the computing experience of nurses among the nursing community of Curitiba, Paraná.

Methods and Results

This is a survey-type survey, exploratory, with a quantitative approach that uses the descriptive statistics for the analysis of its results. The project was approved by the Research Ethics Committee. 78 nurses filled out the questionnaire at the University Hospital and 260 filled at the Public Health Network. Participants are endowed with both experiences as specific knowledge in any field of nursing knowledge (most have specialist titles, and some are masters and doctors). Overall, they reported the use of computers more for administrative purposes, and less to clinical issues and nursing care records. Participants' responses reveal that their majority does not have formal knowledge in computer science, but declare to have done quick courses on computer applications and read magazines or books on computing.. However, most rated their computing experience to be competent. Most of them declare to use computers often.

Conclusion

Knowing the computing experience of nurses is the first step to an awareness of the presence of ICT in health care. It is a reality that can no longer go back, but also an achievement of individual and organizational professional development goals in health.

Informatics Competencies in Nursing Management

Rodrigo Jensen[a], Christiane Pereira Martins Casteli[bc], Rika Miyahara Kobayashi[c], Maria Madalena Januário Leite[b]

[a] *Botucatu Medical School, Sao Paulo State University (UNESP), Botucatu, Brazil*
[b] *School of Nursing, University of Sao Paulo, Sao Paulo, Brazil*
[c] *Dante Pazzanese Cardiology Institute, Sao Paulo, Brazil*

Abstract

This study aimed to identify in scientific literature the informatics competencies required from the nurses to make decision in management process. Through a scoping review, literature databases were searched to find articles published in Portuguese, English, or Spanish, until July 2013. 188 articles were found, and seven were included in this study, published between 1994 and 2011. The studies were written in English (5; 71%), in USA (5; 71%), using experience reports or literature review designs (5; 71%). The informatics competences were categorized according the Technology Informatics Guiding Education Reform (TIGER). The findings highlight gaps in informatics competence to make decisions in the management process – essentially in information management competence.

Keywords:
Nursing Informatics; Nursing Administration Research; Professional Competence.

Introduction

The use of computer technologies by nurse managers is increasing exponentially. The aim of this study was to identify in the informatics competencies required from the nurses to make decisions in the management process.

Methods

The scoping review method was used to answer the research question: What informatics competencies are required from nurses to make decisions in the management process? Articles published until July 2013, described in Portuguese, English and Spanish, in CINAHL, Embase, LILACS and PubMed databases were searched. We found 188 articles related to decision-making in the management process developed by nurses supported by informatics competencies. Articles with educational or clinical foci were excluded. In the first round, titles and abstracts were evaluated and 172 articles were excluded. In the second round, 16 full-text articles were read and evaluated by peers, and nine were excluded. Seven articles included were analyzed and the informatic competences were categorized in Basic Computer Competencies, Information Literacy and Information Management, according to the TIGER initiative[1].

Results

Seven articles published between 1994 and 2011 – predominantly in English (5; 71%), from USA (5; 71%), and with low level of evidence, using experience report/literature review designs (5; 71%) – were included. The following informatics competencies and skills were required of the nurse managers:

- Basic Computer Competencies: skills to use the Internet, spreadsheet, graphs, social networks, and databases;
- Information Literacy: skills to use minimum data sets, telemedicine, and evidence-based practice to decision-making, and ensure the quality of information;
- Information Management: skills to use algorithms, decision support systems, and information systems; and to use systems that can maximize clinical outcomes and reduce costs.

Conclusions

In the literature, discussions about how informatics competencies can support the decision-making of nurses in management process are still insufficient. The findings highlight gaps in informatics competence to make decisions in the management process, and essentially in information management competence. The articles showed the importance of infrastructure and education processes to develop informatic competences in health.

Health Informatics Competences for eHealth: What Can We Learn From a Bibliometric Analysis?

Peter Kokol[a], Helena Blažun[b], Kaija Saranto[c]

[a] *Univerity of Maribor, Faculty of Electrical Engineering and Computer Sciences, Maribor, Slovenia*
[b] *Univerity of Maribor, Faculty of Health Sciences, Center for International Cooperation, Maribor, Slovenia*
[c] *University of Eastern Finland, Department of Health and Social Management, Kuopio, Finland*

Abstract

The appearance of eHealth adds a new dimension to health informatics competencies – they are not necessary just for health providers and health information system users and developers, but also for health consumers.

Keywords:

eHealth; Bibliometric mapping

Introduction

eHealth has gained a lot of attention on different fronts and hence a need for new health informatics competencies has arisen. Kokol et al. **[1]** had performed a bibliometric analysis about nursing informatics competences. The aim of this paper is to generalize this kind of analysis to other healthcare professionals in the context of eHealth.

Material and methods

Two corpuses were formed from the Scopus and Elsevier bibliographic databases. HICSC was searched using "(*medical OR health OR nursing OR clinical) AND informatics* AND (competency* or skill*)) strings.". EHCSC was searched using the search string of "(*medical OR health OR nursing OR clinical) AND informatics* AND (competencies* or skill*)) AND eHealth". Corpus data were recorded in an Excel document; preprocessed using built-in Excel functions and then transferred into VosViewer [2] for bibliometric mapping.

Results and discussion

The search was performed on 16th of November 2014. The HICSC consisted of 1779 and EHCSC of 85 information sources. The trend in both scientific areas is positive, but steadier in health informatics than in eHealth competences/skills. In health informatics competences/skills, the exponential trend started in 1990 and became steady in 2004. In the same year the exponential trend in eHealth competencies/skills started. The delayed start of research literature production in eHealth competences in regard to health informatics competences is congruent with the more intensive start of the eHealth research literature production in general.

The information sources from health informatics competences were written by authors affiliated in 86 different countries and from eHealth competences in 29 countries. The vast majority of papers were published in the United States, followed by United Kingdom, Canada and Australia. Bibliometric mapping produced following clusters from HICSC abstracts:

- **Information cluster** combining information with evidence, intervention and patient;
- **System cluster** linking system with the hospital, database and computer;
- **Nursing cluster** associating nursing with informatics competency and computers skill;
- **Education cluster** combining medical/ health informatics and electronic health record with health care and health professionals

and five clusters from EHCSC abstracts:

- **Nursing cluster** linking nursing practice with competency and electronic health record;
- **Education cluster** combining medical education with medical/ health informatics and information technology;
- **Technology cluster** associating technology with woman and smartphone;
- **Internet cluster** linking Internet with health information and college student and
- **Disease cluster** combining health care, training, diagnosis with computer science.

Comparison of HICSC and EHCSC clusters reveals a considerable difference between the research topics in the two fields of our study. The eHealth competence/skills field is oriented toward Internet, technology and diseases and the health informatics competences/skills field is directed more to systems and information.

Conclusion

The present study highlighted that one of the central concepts in health informatics research, namely electronic health records is placed in different contexts within both studied areas. This is an important discovery leading to the conclusion that to achieve the goals of patient centred paradigm, research endeavours in both studied fields should be united.

Education, Technology and Health Literacy

Kurt Lindgren[a], Ina Koldkjær Sølling[b], Per Carøe[b], Kirsten Siggaard Mathiesen[b]

[a] *Department of Technology and Business, University College of Northern Denmark, Denmark*
[b] *Department of Nursing, University College of Northern Denmark, Denmark*

Abstract

The purpose of this study is to develop an interdisciplinary learning environment between education in technology, business, and nursing. This collaboration creates natural interest and motivation for welfare technology. The aim of establishing an interaction between these three areas of expertise is to create an understanding of skills and cultural differences in each area. Futhermore, the aim is to enable future talents to gain knowledge and skills to improve health literacy among senior citizens. Based on a holistic view of welfare technology, a Student Academy was created as a theoretically- and practically-oriented learning center. The mission of the Student Academy is to support and facilitate education in order to maintain and upgrade knowledge and skills in information technology and information management related to e-health and health literacy. The Student Academy inspires students, stakeholders, politicians, DanAge Association members, companies, and professionals to participate in training, projects, workshops, and company visits.

Keywords:

Informatics; innovation; education; training; interdisciplinary; health information technology; m-health; e-health; healthcare; health literacy; participatory health.

Introduction

Population aging leads to considerable pressure on health expenditures because elderly people are living longer with chronic diseases. There is an assumption that welfare technology can provide cost-effective solutions and have a positive impact on the participatory health of elderly people. Training and education of health care professionals is needed to ensure they possess skills to meet future health care demands [1].

Methods

The Student Academy is an interdisciplinary learning environment with a holistic understanding of technology based on the Leavitt-Ry organizational model [2].

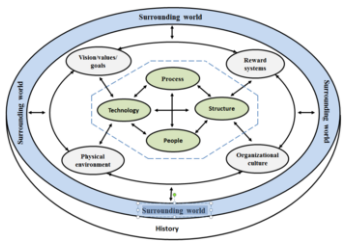

Figure 1: Leavitt-Ry model of organization [2].

The learning and training focus on a user-driven and innovative approach to welfare technology. Students from technology, business, and nursing upgrade their professional knowledge and skills in information technology and information management. Companies and health professionals participate in theoretical and practical training, projects, workshops, and company visits. A collaboration was established with DanAge Association (NGO) to develop competencies in e-health and health literacy. 114 students, 18 teachers, four companies, politicians and six from DanAge have participated in the Student Academy.

Results

Based on observations and feedback the knowledge and skills of the students have improved. The interdisciplinarity and the collaboration with health professionals' companies and the DanAge Association has estabilised an understanding of how technology can support the participatory health of elderly people with chronic disease. In an innovative process, six student groups developed a company's business plan for a new robot designed for rehabilitation.

Conclusion

An interdisciplinary learning environment was established between education in technology, business, nursing, stakeholders, politicians, DanAge Association, and companies. This collaboration created innovation, talents, knowledge, and skills related to e-health and health literacy among senior citizens.

Current Status for Teaching Nursing Informatics in Denmark, Canada, and Australia

Inge Madsen[a], Elizabeth Cummings [b], Elizabeth M. Borycki[c]

[a] *Centre of Clinical Guidelines, Department of Health Science and Technology, University of Aalborg, Denmark*
[b] *School of Health Sciences, University of Tasmania, Tasmania, Australia*
[c] *School of Health Information Science, University of Victoria, Victoria, BC, Canada*

Abstract

Nursing schools in Denmark, Canada, and Australia are all currently involved in integrating nursing informatics in the nursing bachelor programme. This paper gives a brief update on the current situation of nursing informatics education for bachelor level nurses in each of the three countries. Whilst there are differences in the curriculum in each county, it is important to share knowledge about undergraduate nursing informatics worldwide to ensure consistency.

Keywords:

Nursing informatics, bachelors programme, curriculum

Introduction

The explosion in information technology systems in the healthcare setting has resulted in a transformation of work practices. Nurses therefore need knowledge, skills, judgment, and understanding of the importance of informatics from the commencement of their training. This paper is a brief description of the current uptake of nursing informatics (NI) for undergraduate students in Denmark, Canada, and Australia.

Materials and Methods

A review of the published and grey literature was conducted. More specifically, the authors searched the following databases: CINAHL and Medline using the terms: "nursing", "informatics", "Canada", "Denmark" and "Australia". Grey literature was also reviewed.

Results

Nursing informatics is a topic area that needs to be integrated into the nursing curriculum internationally; however, each country has achieved different levels of integration of informatics into their degrees.

Denmark The order of nursing curriculum describes that the program in nursing informatics is to qualify the students in the theoretical and clinically technological development and to meet the people's need for nursing informatics. [1] Nursing informatics is placed in the bachelor's program, 18 months after start and holds two 2 ECTS – points (27 lessons).

Canada In 2012, the Canadian Association of Schools of Nursing (CASN) and Canada Health Infoway developed Nursing Informatics Competencies for Entry-to-practice Registered Nurses [2] and learning tools and resources that can help faculty to with teaching students undergraduate nursing informatics (see 2,3). CASN is actively involved in supporting faculty in a peer to peer network to help faculty master nursing informatics competencies and integrate them into nursing curricula across the country. Peer leaders are engaging nursing faculty across the country [3].

Australia In 2012 the Australian Nursing and Midwifery Accreditation Council released new standards for accreditation of nursing education. These standards include the requirement that student nurses have "familiarity with health informatics, including person-controlled electronic healthcare records" [4]. The importance of developing "the capacity to innovatively use information technology and electronic resources to research the growing evidence base for improved care and treatment methods" [4] is also acknowledged. As a result of this upgrade to the standards it is not possible for a nursing degree to be accredited in Australia unless it includes informatics.

Findings

Differences in the development, evolution and integration of nursing informatics into undergraduate education between the countries exist. Denmark has integrated nursing informatics successfully into the bachelor program. Canada and Australia have recently commenced this process. It is evident that the sharing of information about best practice in curriculum development in integration of informatics will enhance the uptake of this important area in undergraduate degrees.

Trends of Patient Safety Topics Addressed in the Past Five MEDINFO Congresses

Qiyan Zhang [a], Hiroshi Takeda [a]

[a] *Graduate School of Health Care Sciences, Jikei Institute, Osaka, Japan*

Abstract

Health informatics has been promoted as a core curriculum in our patient safety program for four years. There is a need to let students understand how such topics were addressed with relevant literature of trends in medical informatics. In this study, we performed a content analysis by searching the past five MEDINFO Congress Proceedings. We used MeSH Terms or Keywords to search the study subjects and divided them into three categories. 76 subjects were identified, among which 16 were assigned to Category 1 (System-related), 26 to Category 2 (Database-related), and 34 to Category 3 (Others). Some socio-techical issues that emerged in Category 3 presented as future research interests.The identified topics reflect research trends in patient safety.

Keywords:
Patient Safety; Education; Medical Informatics.

Introduction

Health informatics has been promoted as a core curriculum in the Jikei Institute for four years.[1] There is a need to let students understand how informatics topics were addressed with relevant literature regarding trends in eHealth in general. A recently published systematic overview indicates that there is a large volume of work studying the impact of eHealth on the quality and safety of health care.[2] "What is the perspective of medical informatics within this field?" should be asked to help our students to gain domain knowledge. In this study, we performed a content analysis through checking the related topics presented in the past five MEDINFO Congress.

Methods

Pubmed's Advanced Builder was used to search the study subjects. We used Text Words – e.g., "safety" or "error" or "accident" or "incident" or "adverse" or "risk management" – to identify patient safety topics published in the "Journal of Studies in Health Technology and Informatics," volumes 84, 107, 129, 160, and 192. Then, we screened MeSH terms (Volumes 84, 107, 129, and 160) or Keywords (Volume 192), which each contained identified subjects with the aforementioned Text Words to make reconfirmation. Next, we divided the refined subjects into three categories, e.g., Category 1 (System-related), which included MeSH Terms or Keywords like EHR, HIS, Computerized Medical Record Systems, Medical Order Entry System and text words containing "system"; Categoty 2 (Database-related), which included MeSH Term or Keywords like Artificial Intelligence, Knowledge Base, Natural Language Processing (NLP), Data Mining (DM), Information Storage and Retrieval, Decision Support System or Technique; Category 3 (Others), for those topics that belong to neither Category 1 nor Category 2.

Results

In total, 76 subjects were identified, among which 16 were classified in Category 1, 26 in Category 2 and 34 in Category 3 (Table 1). 31 out of 76 subjects were medication safety related, of which 21 are in Category 1 and Category 2, and 10 are in Category 3, respectively. Some socio-technical issues (in Category 3) – for example; quality assurance, quality control, task performance analysis, practice management, workload, interdisciplinary communication, and inter-professional relations – emerged as new foci in this field.

Table 1– Patient Safety Topics Identified in the Past Five MEDINFO Congress Proceedings

Category	MEDINFO 2001	MEDINFO 2004	MEDINFO 2007	MEDINFO 2010	MEDINFO 2013
Category1	0	5	6	1	4
Category2	1	4	5	10	6
Category3	0	5	3	10	16

Discussion and Conclusion

Patient safety has been an increasing concern in the field of medical informatics during the past fifteen years. Medication safety was highly addressed on the implementation of computerised physician order entry (CPOE) systems, and application of decision support technigues to prevent error and manage risks. DM- and NLP-related methods were widely applied to detect adverse drug events. Some socio-techical issues emerged in Category 3, which presented as research interests that need to be explored further. Our findings also showed that evidence for the clinical benifical impact of such technologies is still limited. Patient outcomes in particular are seldomly being assessed in these studies. Academics in health informatics should raise more awarenesses to such problems. Future eHealth technologies are expected to be truly benifical to patients in terms of quality and safety.The topics reflect research trends and can support education in this field.

Abstract

***Objectiv**e: Promote mobility between South-South and South-North for improving level of researchers, staff and students through a platform.* ***Methods**: The methodology is based a filling of a questionnaire about offer or demand. Material is composed a computer connected Internet.* ***Result:** we registered about 203 demands and 31 offers from partners.43 mobilities were executed completely.* ***Conclusion:** The results indicate a real need of mobility for researchers and health professionals in Africa. The important number of mobility demands made by external researchers and professionals (from outside the AFRICA BUILD Consortium) may be constrained by the difficulty to find adequate funding.*

Keywords:

Personel mobility; Health; Africa Build Project.

Introduction

Scientific research is the key to change as it is on research's validated outcomes and reflections on reality that policy makers can base their decisions. At university, scientific research allows students to improve their knowledge [1].

One of AFRICA BUILD project objectives is to facilitate the mobility between learners.

Methods

The hardware consists of a platform via a computer connected to the Internet. This platform had a demand or offer form (depending on the chosen necessary) that the interested have to fill [3].

Definition of mobility

In AFRICA BUILD, mobility (or exchange programs) was defined as the exchange of students and other forms of personnel mobility aiming to conduct a training or research task in other organization.

Results

Forty three (43) mobility initiatives were completed including cases of North-South, South-North and South-South mobility (table 1). Health informatics was the more representative field of interest for this mobility with a total of 13 cases (Table 2).

***Table 1**: Completed mobilities by type*

Mobility type	Number of mobilities
North-South	12
South-North	14
South-South	9
Other*	8
TOTAL	43

***Table 2:** Completed mobilities initiatives by fields*

Fields	Frequencies	Percentages (%)
Health Informatics	13	30.23
Public Health	3	6,98
Elearning	9	20,93
Other	18	41,86
Total	43	100

Conclusion

The results of this work show that mobility is an interesting alternative for capacity building of individuals and strengthening institutions.

Acknowledgments

This study was conducted as part of Build Africa, funded by the FP7 program of the EU.

Middleware Supporting Next Generation Data Analytics in Australia

Douglas I. R. Boyle[a]

[a] *Health and Biomedical Informatics Centre, The University of Melbourne, Australia*

Abstract

In Australia, as a result of the distributed, often private nature of health provision, tight privacy legislation, even tighter organizational policies, access to data covering the whole patient journey of care is a common aspiration that has been almost impossible to achieve. Access to primary care data in a manner that is record-linkable has been a particular challenge. Since 2006 The University of Melbourne has been developing GRHANITE™ Middleware and GRHANITE™ Data Linkage technologies designed to overcome these barriers. With over 10% of Australian primary care data now being routinely extracted utilising this technology, we believe the principal technical challenges have now been overcome. We believe this technology to be at the forefront ethically of providing data for research. This poster describes the principal issues involved and the approaches taken in the technical solution underpinning GRHANITE™.

Keywords:
Data Integration; Primary Healthcare; Linked health data.

Introduction

Australia is a naturally conservative country with conservative privacy, security and consent policies. There are over 7,000 primary care businesses each of whom need to separately grapple with issues of the law, privacy and consent. With no central policies, accreditations or regulations, practices are conservative – and linkable data for research has been nearly impossible to obtain. The GRHANITE middleware system is a major initiative by the University of Melbourne to address the issues of data linkage and to address the many logistical issues in ethically obtaining and utilising the big hole in Australian Health Data Analytics – Primary Care.

Methods

Australian GP systems exhibit no standards in technology, almost no standards in data representation or coding and no accreditation processes. GRHANITE™ deals with these issues through its generic ability to link to almost any technology – and to extract data in raw form allowing interpretation to happen later. This helps resolve problems regarding a lack of IT knowledge in the practice. GRHANITE™ implements opt-in, opt-out and waiver of consent mechanisms - unusual for middleware and project-specific ethics requirements, aggregations and rules can be applied before data transmission. These are the principal components that help reassure practices regarding GRHANITE™ implementations. Study protocols and software can be remotely updated lowering support overheads as is necessary in implementations spanning 100's sites. A privacy-protecting hashing algorithm allows data to be linked to non-GP data sources allowing linkage to happen in this sector for the first time without opt-in informed consent. All communications are encrypted. Delta processing means only data changes are exported lowering bandwidth overheads. The poster shall explain the principal GRHANITE components and architecture.

Results

GRHANITE has been implemented in over 650 sites across Australia and interfaces to eight of the principal GP systems covering over 95% of the Australian GP market. Approximately 40 other interfaces have been developed crossing other health sectors. The collections now have the majority of the GP medical record for nearly 10% of the Autralian population. Initial studies utilizing GRHANITE are now reaching maturity.

Discussion and Conclusion

The poster will describe in detail the many challenges that need addressed to ethically extract data from primary care in Australia – a complex task with over 20 man-years development to achieve. A fast growing level utilisation of GRHANITE across the sector helps validate the mechanisms undertaken to address the challenges present – and in doing so formalises the challenges. The GRHANITE record linkage tool is probabilistic and this generally rules-out clinical data sharing applications including acting as a Health Information Exchange. Because the data exported is generic and raw, the use of GRHANITE requires good analytic skills – BI tools and data interpretation are not roles GRHANITE fulfills.

Many countries may be able to implement systems with fewer legislative and policy barriers. The fact that this tool is able to navigate so many barriers suggest to us that the GRHANITE system is a leader in the field of ethical large-scale data provision for audit, research and health surveillance. Even where legislation or policy restrictions allow more flexibility, a GRHANITE implementation may help raise the bar.

Proposal of Local Automatic Weighing Attribute in CBIR

David Jones Ferreira de Lucena[a, b], Marcelo Costa Oliviera[a, b], Aydano Pamponet Machado[b]

[a] *Lab of Telemedicine and Medical Informatics at University Hospital HUPPA/UFAL/EBSERH*
[b] *Computing Institute, Federal University of Alagoas, Brazil. {davidjones, oliveiramc, aydano}@ic.ufal.br*

Abstract

Lung cancer is the most common malignant lesion and the principal cause of cancer-related death worldwide. This problem encourages researchers to build computer-aided solutions to help diagnose lung cancer. Content-based image retrieval (CBIR) systems are very promising in this context due to a large number of image generated everyday. However, semantic gaps have limited CBIR applicability. This work proposes a new approach to automatically adjust CBIR attribute weights to reflect users' semantic interpretation on retrieval process, minimizing the semantic gap problem and improving retrieval accuracy.

Keywords:

Content-based image retrieval; information retrieval; decision support; update weighing attributes; lung cancer.

Introduction

Currently, lung cancer is the principal cause of cancer-related death. Some characteristics like the aggressive and heterogeneous nature, small size (less than 3mm in initial stages) and location in anatomic complex structures have imposed difficulty for mortality reduction by early diagnosis.

In the last decade, techniques based on computer vision, image processing and pattern classification have been applied to assist in the diagnosis process, providing a second opinion to radiologists. CBIR is one of the most promising approaches in this context due to the large amount of images generated. CBIR is a framework that could provide support retrieving images based on image content or on metadata associated to an image. Retrieving similar exams to a new one based on similarity criteria allow specialists to check another exams to assist them on decision making. Despite this, CBIR has a semantic gap problem. On the other hand, there is a gap between the users' subjectivity and feature used by computational algorithms to represent objects mathematically.

In order to minimize semantic gap, we propose an automatically updated weights of features based on local learning, aiming to represent users' sermantic interpretations and retrieve nodules with same malignancy and visually similar.

Materials and Methods

The image database utilized was the Lung Image Database Consortium (LIDC). It has two important properties of the nodules: margin manually segmented and malignancy associated to each nodule. In previous work[1], the preprocessing phase performed aimed to extract 36 texture attributes (TA) of each nodule based on a 3D co-occurrence matrix.

The proposed processing began normalizing the TA database and divided it into two balanced parts: a training and evaluation database. Next, sequential training and evaluation steps where the evaluation function (EF) increased (Figure 1). When the process stopped, we found that the weight vector learned from subjectivity in malignancy determination.

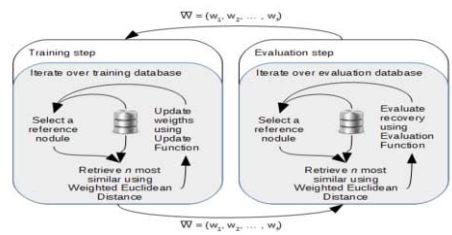

Figure 1 - Update weight process workflow

The local property of this proposal is based on using only the *n* most similar nodules to update weights, compared to utilizing all examples from a dataset for global methods. Considering its neighborhood, the weights were updated as shown in Equation (1). In order to accompliish, we calculated the inverse pattern deviation (IPD) of attribute projection a_i from *n* most similar nodules recovered by the weighted euclidean distance (WED). IPD has been used to minimize the variability in a_i, because intuitively as the variability increases, the relevance of attribute a_i decreases, and vice versa. The update rate determines how much change in each iteration.

$$w_i' = w_i + \alpha\left(\sigma_i^{-1} - w_i\right) \quad (1)$$

During the evaluation process, retrieval order and relevance of nodules was very important. The EF used an amortization rate ( ) to give more influence to top positions and assigned a score value (*s*) associated to nodule relevance, as show in Equation (2).

$$E(\overline{w}, \overline{x}) = \sum_{j=1}^{n} \gamma^j s_j \quad (2)$$

Conclusion

With this work, we aimed to contribute to the advancement of CBIR, giving an automatic solution to adjust attributes' weight in order to improve retrieval precision of similar objects and to minimize the semantic gap influence.

Ontology-Driven Semantic Search for Brazilian Portuguese Clinical Notes

Sadid A. Hasan[a], Xianshu Zhu[a], Joey Liu[a], Claudia M. Barra[b], Lucas Oliveira[b], Oladimeji Farri[a]

[a] *Philips Research North America, New York, United States*
[b] *Pontifical Catholic University of Paraná, Curitiba, Brazil*

Abstract

The emerging penetration of Health IT in Latin America (especially in Brazil) has exacerbated the ever-increasing amount of Electronic Health Record (EHR) clinical free text documents.This imposes a workflow efficiency challenge on clinicians who need to synthesize such documents during the typically time-constrained patient care. We propose an ontology-driven semantic search framework that effectively supports clinicians' information synthesis at the point of care.

Keywords:

Natural Language Processing (NLP); Semantic Search; Ontology Classification; Brazilian Portuguese

Introduction

Traditional semantic search applications mainly focus on the general knowledge domain while understanding the English language. Furthermore, existing semantic search applications based on Brazilian Portuguese are not designed to support routine healthcare tasks and clinical workflow. We propose an ontology-driven semantic search framework to provide clinicians better support in their decision-making process.

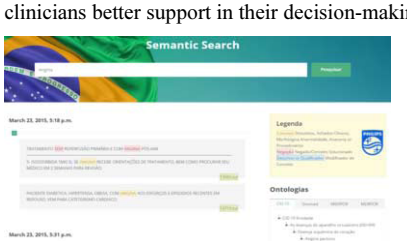

Figure 1 - Screenshot of semantic search user interface

Methods

Our semantic search framework uses open source NLP toolkits to analyze the Brazilian Portuguese grammar. The resulting grammatical units are processed for clinical concept extraction and mapping to Concept Unique Identifiers (CUI) in the Unified Medical Language System (UMLS) Metathesaurus. We generate relevant hierarchical representations of clinical concepts in the Portuguese version of the International Classification of Diseases (CID-10) based on publicly available language translations, and mapped these concepts to their English equivalents within the UMLS, including the Portuguese clinical ontologies: MSHPOR (Medical Subject Headings in Portuguese) and MDRPOR (Medical Dictionary for Regulatory activities in Portuguese). CID-10 concepts are then mapped to the Systematized Nomenclature of Medicine – Clinical Terms (SNOMED CT). Our ability to achieve Portuguese-English mapping of controlled clinical vocabularies represents a significant contribution to Brazilian Portuguese clinical NLP research. Our framework also offers patient data visualization via an intuitive search engine interface (Figure 1) that allows clinician users to efficiently retrieve relevant clinical information from large data sources.

Results

To evaluate the effectiveness of our semantic search framework, we conducted a pilot study using a subset of 80 cardiology discharge summaries written in Brazilian Portuguese. 4 clinical students (2 Medical and 2 of a Nursing background) were each asked to perform 2 clinical summarization tasks using a traditional EHR-like system (without semantic search functionality) for one task and our semantic search system for the second task. Our study results showed that on average, the students required 39.9% less time to complete task 1 and 10.7% less time to complete task 2 when they used our semantic search application. Further analysis of the results suggested that the differences in time to task completion may be due to each student's decision to read every discharge summary while using the traditional EHR-like system. In addition, qualitative data from the interviews conducted after task completion revealed that the students unanimously preferred having access to the semantic search application for task completion as they could search for keywords and browse through fewer summaries in contrast to manually synthesizing information. Limitations in our study include possible disparities in domain expertise, documentation speed, degree to which the tasks were understood by the students, and differences in task complexity. In our future research, we would perform a larger and more robust evaluation of our application while minimizing the aforementioned limitations.

Conclusion

Preliminary evaluation of our ontology-driven semantic search framework for Brazilian Portuguese clinical documents reveals that it effectively improves clinical task workflow and can contribute to the decision making process of the clinicians through faster, and more accurate information retrieval and visualization at the point of care.

Use of Self-Service Query Tools Varies by Experience and Research Knowledge

Gregory W. Hruby[a], Jessica Ancker[b], Chunhua Weng[a]

[a] *Department of Biomedical Informatics, Columbia University, New York, NY, USA*
[b] *Department of Biomedical Informatics, Cornel University, New York, NY, USA*

Abstract

The lack of understanding of user experience with self-service query tools is a barrier to designing effective query tools and is what propelled this study. User actions were documented and transformed into networks of actions for qualitative analysis. Proficient use of self-service query tools requires significant technical experience. To decrease the user learning curve, additional user education is necessary for novice users.

Keywords:
Query Tools; Expert and Novice Users.

Introduction

A major challenge to clinical and translational research resides in facilitating access to EHR data for researchers [1]. Self-service query tools (SSQT) have been developed to meet this need among diverse users [2]. Understanding how diverse users interact with SSQTs can inform designs for effective query tools in the future. Therefore, this study reports user experiences across SSQTs and research knowledge.

Methods

Eight semi-structured interviews and user observations were performed at four academic institutions. Users (physicians, clinical researchers, EHR data analysts) were divided into two sub-groups, experts and novices, based on having greater than 2 years of experience with research and the SSQT. Users were asked to perform a query to resolve their real-world information need using think-aloud protocols. All observations were videotaped to capture the actions and thoughts of the user. When the user completed the query, an exit interview was performed. A user-action schema was iteratively developed and pruned for video annotation. For each video, user actions were annotated with this schema by a single annotator, and then repeated for quality control. For each expert and novice group across research knowledge and SSQT experience, normalized directed network graphs were produced and user-action tables were created.

Results

We identified four user actions: browse, enter, review, and select, which had three, four, five, and nineteen subtasks, respectively. As shown in Table 1, expert and novice users had similar frequency distributions among actions. Expert researchers extensively used the action "Enter 'Search Criteria,'" while novice researchers rarely did.

Table 1 – User-Actions by SSQT experience and research knowledge

User-action	Research Knowledge		SSQT Experience	
	Expert (n=5)	Novice (n=3)	Expert (n=3)	Novice (n=5)
Browse	7	11	8	9
Enter	10	9	12	8
Review	4	5	4	4
Select	33	54	42	40

The directed network graphs produced show patterns of user-actions within our groups. Most notably, SSQT experts exhibited a more organized flow of user actions. They added data elements rather than removed them after reviewing the query build, and also tended to reformulate their queries after obtaining a result set. SSQT novices seemed to augment their queries by adding or removing data elements after reviewing their query build. Interestingly, research knowledge did not display varying patterns of user-actions. Both expert and novice researchers used the SSQT in a similar pattern.

Conclusion

As expected, SSQT experts seem to be more efficient with their actions when completing a query, implying that an improved user experience may be related to user education of the SSQT functionalities and uses. Additionally, SSQT experts seem to augment their query more often after reviewing query results. Finally, there seemed to be minimal differences between the user-action pattern of research experts and novices. However, research experts frequently performed data element searches rather than browsing.

Comparision and analysis of top 10 exercise android Apps in mainland China

Yanling Wang[a], Liu Sun[a] , Yahong Xu[a] , Qian Xiao[a], Polun Chang[b], Ying Wu[a1]

[a] *School of Nursing, Capital Medical University, Beijing, China*
[b] *Institute of biomedical informatics, National Yang-Ming University, Taipei*

Abstract

Medical guidelines highly recommend physical activity and aerobic exercise in the prevention of primary and secondary cardiovascular disease. The use of exercise-promoting application software may improve clinical outcomes for cardiovascular disease (CVD) patients. The study aimed to compare and analyze the functions of the top 10 exercise Android Apps which had more than 1,000,000 downloads from the main four Android App stores in mainland China. The results showed that most of these popular apps had pedometer, exercise plan preset, user data presentation, user encouragement and community sharing functions while a few of them had exercise video clips or animation support and wearable devices. Given these data, the conclusion is that these popular apps fulfill some of the functions recommended by medical guidelines, however, lack of some functions such as pre-exercise risk assessment, the exercise intensity recording, specific instructions by professionals, and monitoring functions for CVD patients.

Keywords:
Exercise; Android; App; Health;CVD

Introduction

It is recommended that CVD patients engage in 3 to 4, 40 minute sessions per week of moderate-to-vigorous physical activity[1]. However, most patients do not satisfy these recommendations. It is proposed that the use of exercise apps by CVD patients may improve adherence to an exercise schedule, but it is unclear whether popular apps have the appropriate functions to support the CVD patient in fulfilling recommended physical activity guidelines.

Materials and Methods

The top 10 exercise apps were selected from Android App stores, which include Tencent, 360, Baidu, and 91 in China, all of which had more than 1000,000 downloads in the main Android App stores (by the time 19th Dec 2014). The data were stored and analyzed using Excel software.

Results

The general information of the top 10 android Apps is shown in Table 1. The main funtions of these apps are illustrated in Figue 1. Most of the top 10 apps have pedometer, exercise plan preset by users, user data presentation, user encouragement functions while a few of them had exercise video clip or anination support and wearable devices.

Conclusion

The top 10 Android Apps have some functions that can be used to assist CVD patients in meeting recommended physical activity guidelines, however, there is still a need to develop some special functions for patients with CVD.

Table 1– General Information on the top 10 Android Apps

App Names	Ver	Size (Mb)	Downloads（10,000） Tencent	360	Baidu	91
Sythealth	3.6.2	9.68	253	331	4280	>50
Gudong	5.2.0	17.81	114	269	320	>100

3D Printed Models and Navigation for Skull Base Surgery: Case Report and Virtual Validation

Lucas E. Ritacco[1], Federico Di Lella[2], Axel Mancino[1], Fernan Gonzalez Bernaldo de Quiros[1], Carlos Boccio[2], Federico E. Milano[3,4]

[1]Virtual Planning and Navigation Unit, Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina, [2]ENT department, Hospital Italiano de Buenos Aires, Argentina. [3]Virtual Planning and Navigation Unit, Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina. [4]National Scientific and Technical Research Council (CONICET), Buenos Aires, Argentina.

Abstract

In recent years, computer-assisted surgery tools have become more versatile. Having access to a 3D printed model expands the possibility for surgeons to practice with the particular anatomy of a patient before surgery and improve their skills. Optical navigation is capable of guiding a surgeon according to a previously defined plan. These methods improve accuracy and safety at the moment of executing the operation. We intend to carry on a validation process for computed-assisted tools. The aim of this project is to propose a comparative validation method to enable physicians to evaluate differences between a virtual planned approach trajectory and a real executed course. Summarily, this project is focused on decoding data in order to obtain numerical values so as to establish the quality of surgical procedures.

Keywords:
Virtual preoperative planning; 3D printed model; skull base navigation.

Introduction

This study aims to show in a virtual preoperative plan setting, a surgical trajectory through the temporal bone. Afterwards, a printed 3D model is used in order to execute and practice the planning under navigated guideline. Finally, the same planned trajectory is executed in the patient, also under navigated guideline. The objective of this work is to establish a comparative virtual study for testing the results between the 3D planned trajectory and the executed trajectory.

Materials and Methods

A 38 years old man complains about sudden sensorineural hearing loss on the left side associated with tinnitus and transient peripheral facial paralysis in relation to physical efforts. With the diagnosis of cholesterol granuloma, an infracochlear approach was planned for apply a transtemporal tumor drainage assisted with intraoperative navigation.
A plastic 3D model was printed (Figure 1).
First, planning was executed in a 3D model under navigation guidance (Intellect navigation software; Stryker Navigator, Freiburg, Germany). Surgery was simulated by drilling the 3D model [1]. This experiment was carried on using surgical microscope simulating the setting of the operating room.

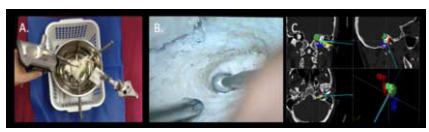

Figure 1- A. Navigating 3D plastic model. B. Drilling plastic model guided by navigation. C. Navigator showed the trajectory planned during the procedure to the surgeon.

Next, the drilled 3D model was CT scanned. Finally, these same steps were applied to the clinical case.
The trajectory discrepancies were measured computing the mean relative euclidean distance from the center line of the planned trajectory to the center line of the executed trajectory.

Results

Differences between the planned and the executed trajectories in the printed model were on average 2.62mm (SD 0.94mm). Differences between trajectory planned and and executed in the post-operative patient model were on average 0.69mm (SD 0.44mm).

Conclusion

We could state that 3D models and surgical navigation tools potentially improve quality and safety for interventions, since surgeons have an intraoperative three-dimensional orientation. It is a major advantage for physicians to work with computer-aided surgery tools since the results of the procedures could be evaluated using the proposed validation model.

Accuracy of Chest Wall Tumor Resection Guided by Navigation: Experimental Model

Lucas E. Ritacco[a], David E. Smith[b], Axel V. Mancino[a], German L. Farfalli[c], Luis Alberto Aponte-Tinao[c], Federico E. Milano[a,d]

[d] *National Scientific and Technical Research Council (CONICET), Buenos Aires, Argentina*

Abstract

Difficulty in identification wall chest tumors lead to unnecessary wide resections. Optical navigation and preoperative virtual planning are assets for surgeries that require exactness and accuracy. These tools enable physicians to study real anatomy before surgery and to follow an established pathway during procedure ensuring effectiveness. The aim of this paper is to demonstrate that Preoperative Virtual Planning is a useful tool in chest tumor interventions to define oncological margins successfully. Moreover, it is possible to use a virtual specimen in order to quantify accuracy. Optical navigation has been used in surgical procedures such as neurosurgery, orthopaedics and ENT over the last ten years. This principle is used in order to orientate the surgeon in three dimensional spaces during the surgery. Surgeons are guided intraoperatively with navigation and are able to obtain a correspondence between images acquired and processed before the surgery and the real anatomy.

Keywords:

Optical navigation; Chest wall tumor; Preoperative virtual planning; Chest wall allograft**.**

Introduction

The main problem of chest wall tumors is the non-visible or non-palpable oncology margins that lead to wide surgical resections. Preoperative planning and navigation introduce a new concept in computer-assisted surgery that consists of using specific tools, which provide safe and accurate localization to optimize the surgical margins while keeping the safety margins unharmed [1]. The objective of this paper is to describe technical aspects and to establish an experimental design in order to demonstrate accuracy in a chest wall navigation.

Methods

The four cases included in this work were patients with a chest wall tumor where the margin cannot be determined using direct visual inspection nor palpable features. A navigated pointer was used to mark the osteotomy, which had been previously planned, on the superficial bone with a surgical marking pen. Next, the surgeons performed the osteotomy following this mark with a freehand saw. After surgery, the surgical specimen was CT scanned, reconstructed and registered to the bone cortex in the plan. A plane fitting algorithm was used to find the precision of the osteotomy (Fig 1).

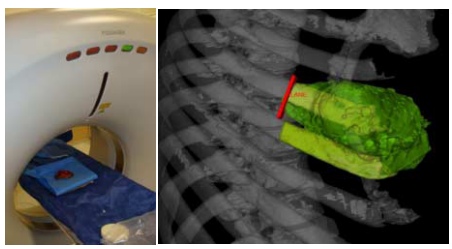

Figure 1 – The specimen is CT scanned and registered (in green) to the preoperative plan (in white) to measure the accuracy and precision.

Results

The accuracy (median) of the osteotomy was of 0.44mm with a precision (equivalent to a 6 sigma dispersion) of 3.78mm. The 99.99966% of the osteotomy surface is below the tolerance threshold of 2mm. In the four cases, it was possible to generate a preoperative plan and achieve a good intraoperative registration between the virtual scenario and the patient.

Conclusion

Navigation is an essential computer-assisted tool for surgery, which should be taken into account in order to assist the surgeon in the operating room. This technique is accurate and reproducible. Furthermore, this tool shows exactness and potentially reduces morbidity during surgery. The present validation model, using a virtual specimen scanned, is an useful and novel method to quantify results after a chest wall tumor resection is executed.

Identification of Incidental Pulmonary Nodules in Free-text Radiology Reports: An Initial Investigation

Lucas Oliveira[a], Ranjith Tellis[a], Yuechen Qian[a], Karen Trovato[a] and Gabe Mankovich[a]

[a] Clinical Informatics Solutions and Service, Philips Research North America, NY, USA

Abstract

Advances in image quality produced by computed tomography (CT) and the growth in the number of image studies currently performed has made the management of incidental pulmonary nodules (IPNs) a challenging task. This research aims to identify IPNs in radiology reports of chest and abdominal CT by Natural Language Processing techiniques to recognize IPN in sentences of radiology reports. Our preliminary analysis indicates vastly different pulmonary incidental findings rates for two different patient groups.

Keywords:

Incidental Findings; Natural Language Processing; Radiology; Patient Care; Algorithms.

Introduction

Due to increasing volume and quality of CT imaging studies, more incidental findings (IFs) are reported by radiology departments [1,2]. An incidental finding is an asymptomatic lesion noted in an imaging study that is unrelated to the 'reason for exam' [1,2,3]. Incidental pulmonary nodules (IPNs) are not unusual IFs for patients presenting with abdominal pain, for example.

IFs are communicated through the free-text narrative radiology report. This makes automated identification and longitudinal follow-up challenging, leading to untimely diagnosis or care delivery. A tool to accurately identify IFs can help the healthcare enterprise assess appropriate recommendations and track follow-ups in their patients. This work describes an initial step to identify IPNs in radiology reports of chest and abdomen CTs by applying natural language processing (NLP) techniques to recognize and quantify IPNs in sentences from radiology reports.

Methods

This study was performed on a sample of 3,785 representative, de-identified chest and abdomen CT reports from an academic hospital in Illinois, US**.** The reports were parsed with a sentence and section detection engine that also normalizes section headers (e.g., 'Clinical History', 'Findings', 'Impressions'). IPNs were detected using one list (L_1) with pulmonary nodule keywords (e.g., mass, lesion, or nodularity) and another list (L_2) with expressions indicating that a pulmonary nodule is not a new finding (e.g., again noted, stable, or previously). Regular expressions were created based on L_1 and L_2 to establish if a word or phrase was contained in a sentence. An IPN is defined as a match of L_1 in the 'Findings' section whose sentence does not match L_2 and the'Reason for Exam' and 'Clinical History' sections had no matches of L_1 indicating any prior pulmonary condition.

For a initial evaluation of the precision of our algorithm, we randomly selected 100 reports for manual review by one of the authors (KT): 50 reports with an IFs identified and 50 reports with no IFs identified.

Results

The results obtained in our preliminary investigation suggested that 9.2% (347/3,785) of reports contained at least one IPN mention. The rate of false positives and false negatives detected in the manual validation were 12% (12/100) and 2% (2/100) respectively. It has been reported [2,3,4] that the rate of IPNs are associated with risk factors such as age, tabacco use and cancer history. The rate of IPNs in reports for oncology patients (i.e., reports containing "metastasis" or "cancer" in *Reason for Exam* and *Clinical History* sections) was 10.8% (276/2,565 reports) compared to 5.8% (71/1,220) for non-oncology patients.

Conclusion

We have an initial NLP method for determining IPNs and we were able to successfully run it on a sizeable corpus of reports producing a rate of IPNs that is different than earlier rates discussed in the literature [2,3.4]. A more specific definition of IFs might be considered to exclude oncology patients. Next steps include further validation with clinical experts and a more expanded statistical evaluation will help assess the true clinical potential of our methods.

Follow-up Recommendation Detection on Radiology Reports with Incidental Pulmonary Nodules

Lucas Oliveira[a], Ranjith Tellis[a], Yuechen Qian[a], Karen Trovato[a] and Gabe Mankovich[a]

[a] *Clinical Informatics Solutions and Service, Philips Research North America, NY, USA*

Abstract

The management of follow-up recommendations is fundamental for the appropriate care of patients with incidental pulmonary findings. The lack of communication of these important findings can result in important actionable information being lost in healthcare provider electronic documents. This study aims to analyze follow-up recommendations in radiology reports containing pulmonary incidental findings by using Natural Language Processing and Regular Expressions. Our evaluation highlights the different follow-up recommendation rates for oncology and non-oncology patient cohorts. The results reveal the need for a context-sensitive approach to tracking different patient cohorts in an enterprise -wide assessment.

Keywords:

Radiology, Incidental Findings, Follow-up Recommendation, Natural Language Processing, Patient Care.

Introduction

Incidental findings (IFs) in radiology reports are image observations that are not directly related to the original aims of the imaging examination [1,2]. Attentive management of IFs after identification may lead to early diagnosis and treatment of disease. Often when IFs are communicated in the radiology report, guideline-specific follow-up recommendations, such as the Fleischner Guidelines [1], are lacking. Clear communication of follow-up recommendations by the radiologist will contribute to timely follow-up of IFs, which may improve patient outcomes, reduce healthcare costs, minimize patient radiation exposure, and avoid costs incurred by litigation for missing IFs [1,2,3]. This work describes an investigation of the IPN follow-up recommendation rate in free-text radiology reports. We present a methodology to automatically identify follow-up recommendations of IPNs in chest and abdomen computed tomography (CT) reports through the use of natural language processing. We then use it to identify follow-up rates for two patient cohorts.

Methods

This study was performed on the complete corpus of 3,785 de-identified chest and abdomen CT reports from an academic hospital in Illinois, US. The reports were first parsed into a sentence, paragraph and sections. The section detector normalizes headers to common sections (e.g., 'Clinical History', 'Findings' and 'Impressions'). Incidental pulmonary nodules were identified in 347 reports using an NLP engine whose internal working/evaluation is not in the scope of this paper.

The follow-up recommendations were detected using a list of commonly used expressions such as 'may be performed', 'follow-up', and 'could be considered'. Regular expressions were created based on this list to identify recommendations in paragraphs from the 'Impression' section.

Patients were categorized into two cohorts: oncology and non-oncology. Oncology patients are identified by phraseology in the 'Reason for Exam' or 'Clinical History' sections having words related to metastasis or cancer, but not lung cancers.

Results

In this evaluation, 9.2% (32/347) of the incidental pulmonary nodules had follow-up recommendations. Oncology patients had a 6.2% (17/276) follow-up recommendation rate, whereas non-oncology patients had a 21% (12/71) recommendation rate.

Conclusion

This study presents a methodology that identifies follow-up recommendation rates in radiologyreports. Over 91.8 % of reports containing pulmonary incidental findings failed to provide a recommendation. For oncology patients, the recommendation rate is especially low, possibly due to comorbid oncological conditions that already require regular follow-up. Our results demonstrate a different recommendation rate for two cohorts of patients. Next steps include further validation of the detection algorithm using multiple radiologist ground-truth annotations.

Clinical Trial Feasibility Study Questionnaire Analysis

Iñaki Soto-Rey[a], Martin Dugas[a], Fleur Fritz[a]

[a] *Institute of Medical Informatics, University of Münster, Germany*

Abstract

With the growing complexity and cost of clinical trials (CTs) over the past few decades, Protocol Feasibility (PF) studies have become one of the most critical CT steps in order to avoid costly protocol amendments and ensure the success of CTs. The PF process includes interaction with clinicians located at targeted clinical sites, which results in slow and cumbersome process steps. These process steps are normally supported by information systems that allow users to create, share and collect responses to feasibility questionnaires. This investigation analyzes the systems and questionnaires utilized at several clinical research companies for PF. In addition, it provides recommendations that could eventually improve current methods and systems in place.

Keywords:

Clinical Trials as Topic, Feasibility Studies, Questionnaires.

Introduction

Clinical trials (CTs) often suffer delays, and their initial budget is adjusted upwards due to both recruitment rates not being met, and costly protocol amendments. A good trial protocol feasibility (PF) study has been proven to be an effective method to avoid such issues.[1]. The design of PF studies is currently supported by clinicians located at the targeted sites, often resulting in slow and cumbersome process steps that involve a great amount of resources and time [2]. This research analyzes common processes, information systems, and feasibility questionnaires (FQs), and advises how they could be improved.

Methods

The European Federation of Pharmaceutical Industries and Associations (EFPIA) companies participating in the EHR4CR project[1] were asked to deliver examples of FQs. Furthermore, we analyzed how they are designed and which process steps are required to obtain their responses. The received FQs and templates were manually reviewed and the following information was extracted: Name and number of sections, question types, and number of questions per section.

Results

Feasibility experts from seven EFPIA companies collaborated in this study. Seven processes, five PF questionnaire templates, and sixteen FQ examples were analysed.

One of the companies uses a word processor to build the FQ, three corporative systems and three free-to-use online survey systems. The number of FQ sections varies between 3 and 13 with one to 47 questions per section and 22 to 100 questions per questionnaire. In Table 1, the question types and number of questions are presented.

Table 1– Question types and number (N) of questions (Q)

Q type	Total QN	Q per template	Q per questionnaire
Free text	532	21,2	26,6
Radio Button	299	13,6	14,4
Radio Button +Comment	251	12	11,9
Number	230	4	13,1
Checkbox +Comment	62	4,8	2,4
Checkbox	14	0,2	0,7
Free text table	12	0,4	0,8
Date	6	0	0,4

Discussion

This research identified a total of eight different question types in FQs, of which free text was the most common one. Most of the companies use templates or pre-defined questions to build the FQs but – even though the questions are frequently repeated – the analysed systems do not use historical records to allow auto-completing answering. Interviewees reported the number of PF design tools and the long-time interval to obtain the FQ responses as the most critical PF design issues.

The use of free text questions should be reduced due to the intricacy of free text answer completion and analysis. Electronic survey systems must be improved with the re-use of historical data to auto-complete responses, which facilitates responding and speeds up the entire PF process.

Conclusion

Free text questions in feasibility questionnaires need to be avoided and PF survey systems need to re-use data to automatize responses. There is need for a system that congregates all features of PF design and streamlines the methods in place.

Extraction Of Adverse Events From Clinical Documents To Support Decision Making Using Semantic Preprocessing

Jan Gaebel[a], Till Kolter[b], Felix Arlt[c], Kerstin Denecke[a]

[a] *Innovation Center Computer Assisted Surgery, Leipzig, Germany*
[b] *ID Information und Dokumentation im Gesundheitswesen, Berlin, Germany*
[c] *Clinic for Neurosurgery, University Hospital Leipzig, Leipzig, Germany*

Abstract

Clinical documentation is usually stored in unstructured format in electronic health records (EHR). Processing the information is inconvenient and time consuming and should be enhanced by computer systems. In this paper, a rule-based method is introduced that identifies adverse events documented in the EHR that occurred during treatment. For this purpose, clinical documents are transformed into a semantic structure from which adverse events are extracted. The method is evaluated in a user study with neurosurgeons. In comparison to a bag of word classification using support vector machines, our approach achieved comparably good results of 65% recall and 78% precision. In conclusion, the rule-based method generates promising results that can support physicians' decision making. Because of the structured format the data can be reused for other purposes as well.

Keywords:

Medical Language Processing; Information Extraction; Electronic Health Records; Drug-Related Side Effects and Adverse Reactions; Clinical Decision Support Systems.

Introduction

Clinical documentation serves as a information source for medical professionals. However, identifying and processing the relevant information is time consuming [1]. To support information retrieval, clinical decision support systems (CDSS) are developed. One major challenge is, that the majority of the data is stored in unstructured, narrative format. Natural language processing (NLP) methods offer a solution for identifying text passages that are relevant to a specific question or task.

In this paper, we introduce a rule-based NLP method for identifying adverse events in clinical documents. These events influence the following treatment and health care planning and thus need to be considered by a physician.

Methods & Materials

In the course of a manual analysis of clinical documents in German with respect to adverse events, we recognized that there are no significant syntactical similarities in the wording of adverse events. For this reason, we decided to chose a semantic approach instead of a syntactical apporach for adverse event extraction. Our approach exploits the terminology server ID MACS® for normalizing and structuring texts semantically. Medical and linguistic concepts are identified. If a medical concept is found, its severity is assessed by analyzing its surrounding linguistic concepts. When certain words express negativity, the passage is stored as an adverse event.

Evaluation and Results

We compared the results of our method with those of a standard machine learning classifier implemented in WEKA [2] using a test dataset of five clinical documents from the neurosurgical department that were annotated by physicians. First, we performed a 10-fold-cross validation with a Support Vector Machines algorithm applied on a bag of words representation of the text. Second, we exploited this trained model to the sentences of the test dataset. The sentences of the test set were also classified using our approach. Precision and recall are shown in Table 1.

Table 1 – Recall, precision, fallout, F-measure

	WEKA	AdverseEvent-Extraction
Recall	0,7647	0,6470
Precision	0,4642	0,7857
F-measure	0,5777	0,7096

Conclusion

We conclude, that an extraction of complex linguistic entities is possible, but not with plain syntactical methods, like assessing word frequencies or regular expressions. A semantic preprocessing of the text and usage of medical terminologies are necessary to achieve good results. Thereby, information extraction systems can combine specific, standardised concepts to complex items or events. The output of such systems includes a semantically structured and normalised representation of the desired information. In this way, the extraction result can be processed further. With our method, the results can be used for calculations as for instance in decision support systems, statistical analysis or administrative calculations.

Development and evaluation of task-specific NLP framework in China

Caixia Ge[a], Yinsheng Zhang[a], Zhenzhen Huang[a], Zheng Jia[a], Meizhi Ju[a], Huilong Duan[a] and Haomin Li[b,c]

Abstract

Natural language processing (NLP) has been designed to convert narrative text into structured data. Although some general NLP architectures have been developed, a task-specific NLP framework to facilitate the effective use of data is still a challenge in lexical resource limited regions, such as China. The purpose of this study is to design and develop a task-specific NLP framework to extract targeted information from particular documents by adopting dedicated algorithms on current limited lexical resources. In this framework, a shared and evolving ontology mechanism was designed. The result has shown that such a free text driven platform will accelerate the NLP technology acceptance in China.

Keywords:

Natural language processing; Information extraction; Clinical task.

Introduction

Directly using data recorded in Electronic Medical Record (EMR) systems for diverse clinical tasks will increase the automation of information systems in healthcare. However, the data formats and structure required by different tasks are seldom fulfilled by most EMRs, especially in Chinese hospitals where most clinical information is recorded in clinical documents using natural language. In this study, we propose a task-specific Natural Lanugage Processing (NLP) framework which customizes algorithms and defines targeted concepts and clinical documents for diverse information extraction tasks. This NLP framework seamlessly integrates with a general CDS framework by sharing a common ontology and provides an evolving approach to accumulating lexical resources.

Methods

Since 2012, we designed and developed a general CDS framework in a 2000-bed hospital. As reported in many studies, many CDS applications that require additional data entry have very poor acceptance in the clinical setting. So, an NLP framework was proposed to automatically extract information and facilitate CDS data entry. In this setting, a homegrown medical ontology that contains clinical concepts, and relationships between concepts, will be used in the CDS platform and is maintained through a web portal. As most information extraction tasks only focus on specific concepts, a task-specific NLP framework with a lexicon self-propagation mechanism was proposed. As shown in Figure 1, by defining NLP tasks to customize NLP algorithms, and targeting document types and related concepts, task-specific concept sets will be generated and used to complement the homegrown ontology. This will make the lexicon meet the requirements of different tasks. Through integration with EMRs, a task monitor was developed to generate tasks when certain types of clinical documents were released. Different NLP task instances will be invoked based on the defined task profiles. In each NLP task instance, targeted concepts will be extracted from specific documents and fed to the platform for the targeted task.

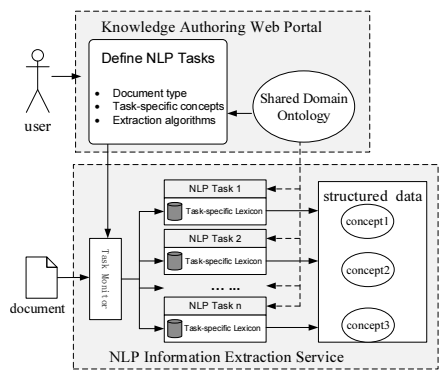

Figure 1- Task specific NLP framework

Users can define new NLP profiles for different tasks. A plug-in mechanism based on the .Net Framework Reflection technology was developed to allow this framework to load and execute third-party NLP algorithms at runtime.

Results

To evaluate this NLP framework we used three different information extraction tasks. In task I, a concept-value pair extraction task that extracts the measurement value of specific concepts from obstetric ultrasound reports was defined. The second task identified adverse drug events (ADE) from progress notes. The last task was to extract general purpose symptoms from progress notes to build a symptom timeline for each patient. The evaluation results are shown in Table 1.

Table 1 - Evaluation Results

	Task I	**Task II**	**Task III**
Recall	97.8%	NA	NA
Precision	98.5%	80.8%	98.2%

Extracting Dependence Relations from Unstructured Medical Text

Charles Jochim [a], Yassine Lassoued [b], Bogdan Sacaleanu [a], Léa A. Deleris [a]

[a] *IBM Research – Ireland, Dublin, Ireland*
[b] *CMRC – University College Cork, Cork, Ireland*

Abstract

Dependence relations among disease and risk factors are a key ingredient in risk modeling and decision support models. Currently such information is either provided by experts (costly and time consuming) or extracted from data (if available). The published medical literature represents a promising source of such knowledge; however its manual processing is practically infeasible. While a number of solutions have been introduced to add structure to biomedical literature, none adequately recover dependence relations. The objective of our research is to build such an automatic dependence extraction solution, based on a sequence of natural language processing steps, which take as input a set of MEDLINE abstracts and provide as output a list of structured dependence statements. This paper presents a hybrid pipeline approach, a combination of rule-based and machine learning algorithms. We found that this approach outperforms a strictly rule-based approach.

Keywords:

Risk; Risk Factors; Artificial Intelligence; Natural Language Processing; Data Mining.

Introduction

Bayesian belief networks are a convenient tool for macro-level risk models, i.e., risk models articulating the dependence between multiple risk factors, diseases and conditions. They have long been advocated as a useful decision and risk modeling framework in medicine [1]. Our focus on automating the extraction and aggregation of risk information seeks to address the practical challenge of building such networks. We focus specifically on the information contained in MEDLINE, which has been steadily growing at a rate of about 1M publications per year in the past few years and for which manual consumption is no longer practical. The larger context of this research is to build a system, called Medical Recap, which automatically extracts risk information from medical papers and then aggregates this knowledge into a Bayesian network.

Methods

This paper focuses on the sub task of extracting dependence information. From the sentence "Smoking increases the risk of lung cancer", we want to extract the relation (Smoking, Lung Cancer). Our approach to this challenge can be divided into two sub-problems: entity detection and relation construction. Entity detection deals with the identification of the elements in a sentence that are part of a relation. Relation construction is about articulating those elements together (which is not straightforward when multiple relations are expressed in the same sentence). We rely on machine learning for entity detection and propose a rule-based algorithm for defining the relations between the extracted entities. More specifically, we have developed a pipeline that identifies sentences containing dependence relations, then identifies the entities (i.e., dependence relation variables) in the sentence using conditional random fields (CRF) [2]. Dependence relations are constructed from the so-obtained entities using a set of rules, which accurately identify correct dependence relations when given the correct entities.

Results

We evaluated our pipeline both after entity detection and after relation construction. The performance of our proposed hybrid approach consistently outperformed a strictly rule-based baseline that uses shallow syntactic parsing. For entity detection, we achieved an F_1 score of 67.1 vs. the baseline performance of 62.6. Likewise, for relation construction using the entities we extracted, we reached an F_1 score of 53.6 vs. a baseline F_1 of 49.1. The results showed that our approach has higher precision and lower recall across the various steps of the pipeline, which is preferred for our particular use case.

In our error analysis of the entity detection we found a number of false negative errors where correct entities were not detected. Sometimes the CRF classifier also had difficulty detecting the correct entity boundaries. These problems were due in a large part to the heterogeneous nature of the entities and the modest size of our annotated corpus.

Conclusion

Our work investigates how to automatically extract dependence information from the academic medical literature, thereby streamlining an otherwise time-consuming and costly process. We developed a set of NLP steps to address this issue and found that our pipeline of algorithms performed satisfactorily especially compared to a naïve baseline.

A Frequency-based Strategy of Obtaining Sentences from Clinical Data Repository for Crowdsourcing

Dingcheng Li[a], Majid Rastegar Mojarad[a], Yanpeng Li[a], Sunghwan Sohn[a], Saeed Mehrabi[a], Ravikumar Komandur Elayavilli[a], Yue Yu[a,b], Hongfang Liu[a]

[a] *Mayo Clinic, Rochester, MN, USA*
[b] *Department of Biomedical Informatics, University of Jilin, Jilin, China*

Abstract

In clinical NLP, one major barrier to adopting crowdsourcing for NLP annotation is the issue of confidentiality for protected health information (PHI) in clinical narratives. In this paper, we investigated the use of a frequency-based approach to extract sentences without PHI. Our approach is based on the assumption that sentences appearing frequently tend to contain no PHI. Both manual and automatic evaluations on 500 sentences out of the 7.9 million sentences of frequencies higher than one show that no PHI can be found among them. The promising results provide potentials of releasing those sentences for obtaining sentence-level NLP annotations via crowdsourcing.

Keywords:

patient health information, clinical notes, high-frequent sentences, bigram filtering, crowdsourcing, de-identification

Introduction

Crowdsourcing has emerged as a popular method to generate training data for machine learning, natural language processing (NLP) and related fields[1,2]. However, in clinical NLP, no one has taken advantage of crowdsourcing since it may reveal the protected health information (PHI). Until now, no de-identification tools could guarantee 100% PHI removal from clinical narratives. Consequently, it remains infeasible to employ crowdsourcing for generating training data for clinical NLP. In this work, we propose a simple frequency-based approach to extract sentences containing no PHI under the assumption that sentences appearing frequently tend to contain no PHI. Based on this approach, it could be possible to generate training data through crowdsourcing for various sentence-level clinical NLP tasks such as concept identification or relation extraction.

Materials and Methods

In this work, we used all of electronic medical records (EMR) extracted from enterprise data trust (EDT) of Mayo Clinic. The EDT stores structured data and unstructured texts from a comprehensive snapshot of Mayo Clinic's service areas. It includes clinical notes, hospital summary, post-procedure notes, procedure note, progress note, tertiary trauma and transfer note. It is composed of 39.7 million records and 1.7 million tokens. We collected high-frequent sentences using following steps: building bigram repository; constructing sentence repository; bigram filtering; sentence frequency filtering and segmentation; dictionary-lookup filtering and sentence distribution analysis.

Experiments

System Results

The running of the above-described workflow yielded about 7.9 million unique sentences with frequencies higher than one (the total number was 276.7 million with an average frequency of 35). We then divided the whole sentence repository into 10 intervals based on log2 frequency. Although the numbers of sentences for each interval were different, we randomly sampled 50 sentences at each interval for evaluation. Meanwhile, we also sampled 200 more sentences the same way from sentences which had passed bigram filtering but only appeared once (the total number of such sentences is 109.2 million) for comparison purpose. Accordingly, the total number of sentences for evaluation is 700.

Manual Evaluation

The 700 sentences were assigned to four experienced reviewers to assess whether PHI could be found among them. In the event that any such information was found, reviewers were required to fill name, profession, location, age, date, contact, ids and comments for other sensitive information into a spreadsheet. The evaluation results (the union of the four reviewers' results), showed that, as expected, most PHI occurred in the first interval. The most frequent PHI element was name – appearing 7, 3, and 2 times in the first, second, and third interval respectively. Similar patterns were seen for profession as well. For age and date, 4 and 13 times were in the first interval and 1 and 3 times in the second interval. No contact was found for all intervals and ids showed one time in the first three intervals.

Conclusion

In summary, we proposed a method based on frequencies to extract sentences containing no PHI from a clinical data repository. We experimented in utilizing Mayo's EDT clinical notes. About 7 million unique sentences which appear more than two times were extracted. The final evaluation on 700 sampled sentences show that nearly no PHI can be found from sentences with higher frequencies (500 of them have frequencies higher than one). As follow-up steps, we will explore ways to make the crowdsourcing for clinical notes realistic and develop corresponding systems.

Extraction of Vital Signs from Clinical Notes

Olga V. Patterson, PhD[a,b], Makoto Jones, MD[a], Yiwen Yao, MS[a], Benjamin Viernes, MPH[a], Patrick R. Alba, BA[a,b], Theodore J. Iwashyna, MD, PhD[c], Scott L. DuVall, PhD[a,b]

[c] Center for Clinical Management Research, VA Ann Arbor Health Care System, Ann Arbor, MI

Abstract

Assessment of vital signs is an essential part of surveillance of critically ill patients to detect condition changes and clinical deterioration. While most modern electronic medical records allow for vitals to be recorded in a structured format, the frequency and quality of what is electronically stored may differ from how often these measures are actually recorded. We created a tool that extracts blood pressure, heart rate, temperature, respiratory rate, blood oxygen saturation, and pain level from nursing and other clinical notes recorded in the course of inpatient care to supplement structured vital sign data.

Keywords:

Natural language processing; Vital signs.

Introduction

To support a study aimed at measuring the prevalence and incidence of sepsis, severe sepsis, and septic shock among veterans, we looked at the availability of vital signs and relevant laboratory data across the Department of Veterans Affairs (VA) medical centers. The VA electronic medical record includes a vital sign package, but we found in an initial assessment that the intensive care units (ICU) of 44 facilities and the acute medical care wards of 7 facilities had less than 80% of patient days where vitals were recorded. Given that it is mandatory for even non-intensive care units to record vitals at least once per shift, and the vital signs are usually summarized in patient care notes, we explored natural language processing (NLP) as a way of filling the gaps in the structured data.

Methods

The initial goal for the NLP system was to extract blood pressure, heart rate, and temperature values from a wide range of clinical notes. A random set of 5,000 documents was selected for a cohort of VA inpatient stays from 2000 to 2012. The documents were manually annotated with instances of vital sign terms and values to serve as a reference standard. The reference standard also included a section header annotation that indicated the beginning of vital signs section. Distinct strings of the vital sign terms were compiled into a lexicon expressed as a set of regular expressions. Analysis of the annotated set revealed a small number of patterns that linked terms and values. The NLP system was built based on the lexicon and patterns collected directly form the annotated corpus. The system utilizes Leo, a set of libraries that enable more efficient utilization of Unstructured Information Management Architecture Asynchronous Scaleout (UIMA AS)[1]. Document review also revealed that other types of vitals signs (weight, height, oxygen saturation, respiratory rate, and pain level) follow the same patterns. So, simply expanding the list of terms broadened the scope of the extraction tool. In order to take full advantage of the expanded scope, another set of 2,000 documents (1,000 training and 1,000 validation) was manually annotated using a broadened list of vital signs.

Additional analysis of vital sign terms and value co-occurrences uncovered that height, weight, pain level, and single values of either systolic or diastolic blood pressure never appeared in text without an associated term, or in very rare cases at least a unit of measure in a close proximity to the value. On the other hand, combined blood pressure (in "120/80" format), heart rate, respiratory rate, temperature, and oxygen saturation may appear as a stream of numbers without the associated terms in context.

The final system included modules to perform the following steps: detecting mentions of vital sign terms and units of measure; detecting numeric values; linking terms and values using patterns; and applying valid range filters on values of each vital sign type.

Results

The system was validated using 1,000 manually annotated documents, distinct from the training set. The tool performance is described in Table 1.

Table 1– Tool performance validated on 1,000 clinical notes

Vital	Recall	Precision
BP Diastolic	0.889	0.919
BP Systolic	0.858	0.927
Temperature	0.879	0.998
Heart rate	0.776	0.917
Pain level	0.454	0.993

Vital	Recall	Precision
Respiratory rate	0.766	0.956
O2 saturation	0.956	0.787
Height	0.800	0.800
Weight	0.824	0.999

Conclusion

Despite the large variability in clinical note content and formats, vital signs tend to appear in a relatively small set of patterns in the inpatient setting, and therefore rule-based extraction of values is both feasible and highly accurate.

Translating ICD-11 into French using lexical-based approach: a preliminary study

[a] *CISMeF & TIBS, LITIS EA 4108, Rouen University Hospital, Rouen, France*
[b] *INSERM, U1142, LIMICS, F-75006, Paris, France*
[c] *Department of Public Health, Saint Etienne University Hospital, France*

Abstract

To translate the 11th edition of the International Classification of Diseases (ICD-11) into French, we proposed a lexical approach using Natural Language Processing techniques. This method relies on the 56 biomedical terminologies and ontologies included in the Cross-lingual Health Multiple Terminologies and Ontologies Portal. From a sample of 336 ICD-11 terms, the algorithm translated 164 (49%) terms into at least one French term each.

Keywords:
Coding System, Mapping, Multilingualism, Semantic Interoperability, Terminology as Topic.

Introduction

The 11th edition of the International Classification of Diseases (ICD-11) is ongoing and its publication is not expected until 2017 [1]. Currently, ICD-11 is neither tranlated into French nor included in the Unified Medical Language System (UMLS). Thus, we have attempted to apply a lexical approach to translate each term from a sample of ICD-11 terms into at least one French term.

Materials and Methods

To translate ICD-11 terms, we proposed a lexical approach using Natural Language Processing (NLP) techniques. This method relies on 56 biomedical terminologies and ontologies (BMTO) included in the Health Multiple Terminologies and Ontologies Portal (HeTOP) [2]. Compared to UMLS, which includes 164,071 French terms, HeTOP includes 349,311 French terms[1] from BMTO.

This approach [3] helps to normalize all the English terms from the bilingual BMTO (English and French) included in the HeTOP. An algorithm was developed to find the terms most lexically similar to the target terms in the BMTO. When a correspondance was found, it was proposed as a possible translation of the English ICD-11 target term. The normalization process involved stripping genitive marks, transforming plural forms into singular, replacing punctuation, removing stop words, lower-casing each word, breaking a string into its constituent words, and sorting the words into their alphabetic order (see Figure 1). Examples of two ICD-11 term translations are listed in Table 1.

[1] Statistics calculated on preferred terms.

Table 1 - Examples of translation of two terms using lexical approach

ICD-11 term	English term (BMTO)	French term
Intracerebral hemorrhage	intracerebral hemorrhage (MeSH)	hémorragie cérébrale
Hypertensive encephalopathy	Hypertensive encephalopathy (MedDRA)	Encéphalopathie hypertensive

Figure 1 - Example of Normalization process for the ICD-11 term "Hereditary cerebral hemorrhage with amyloidosis, Dutch type"

Results & Discussion

According to our lexical approach, of the 336 ICD-11 terms selected, 164 (49%) terms were mapped from HeTOP and translated into at least one French term each. It is noteworthy that 194 (57%) terms were mapped to at least one English term. However, fifteen of these 164 translated ICD-11 terms (9%) were obtained exclusively from the translations performed by the CISMeF team [3].

Text Mining and Data Modeling of Karyotypes to aid in Drug Repurposing Efforts

Zachary B. Abrams[a], Andrea L. Peabody[a], Nyla A. Heerema[b] and Philip R. O. Payne[a]

[a] *Department of Biomedical Informatics, College of Medicine, The Ohio State University, Columbus, Ohio, USA*
[b] *Department of Pathology, College of Medicine, The Ohio State University, Columbus, Ohio, USA*

Abstract

Karyotyping, or visually examining and recording chromosomal abnormalities, is commonly used to diagnose and treat disease. Karyotypes are written in the International System for Human Cytogenetic Nomenclature (ISCN), a computationally non-readable language that precludes full analysis of these genomic data. In response, we developed a cytogenetic platform that transfers the ISCN karyotypes to a machine-readable model available for computational analysis. Here we use cytogenetic data from the National Cancer Institute (NCI)-curated Mitelman database1 to create a structured karyotype language. Then, drug-gene-disease triplets are generated via a computational pipeline connecting public drug-gene interaction data sources to identify potential drug repurposing opportunities.

Keywords:

Cytogenetics; Karyotype; Text mining; Drug repurposing

Introduction

Cytogenetic data in the form of karyotypes are commonly used in the diagnosis and treatment of many forms of cancer. Karyotype data are expressed in a text-based form that is not machine-readable. This limits the utility of these data for secondary use and research purposes. Utilizing the International System for Human Cytogenetic Nomenclature (ISCN), we developed a parsing and mapping system that allows karyotype data to be represented and analyzed in a computationally tractable manner. A Loss-Gain-Fusion model (LGF) was created that allowed us to represent each karyotype as a binary vector. Each cytogenetic region is represented three times (loss, gain, and fusion) in the model. We utilized the publicly available Mitelman database as a test-bed for analyses, focusing on problems related to drug repurposing.

Materials and Methods

Utilizing our computational model and the Mitelman database, we were able to successfully parse 98% of its karyotypes; of those parsed, 89.4% could be mapped into our binary Loss-Gain-Fusion model. We then classified karyotypes based on their disease labels and filtered out all diseases with less than 50 patients. We then selected genetic aberrations present in 20% or more of the population in which the cytogenetic event led to increased gene expression. Subsequently, we identified all genes in the affected region and found drugs that inhibited the function of the overexpressed gene using publicly available drug data in The Drug Gene Interaction Database (DGIdb). We performed a literature search on these results in PubMed selecting diseases and drugs that did not co-occur and where the disease and the gene had co-occurred in at least one PubMed abstract.

Results

We discovered 68,543 triplets containing (1) a disease, (2) an overexpressed gene, and (3) a drug that suppressed that specific gene. From this list, we discovered a total of 69 cancer disease-drug pairs that were not cited as co-occurring in the literature. Given this filtering process where the drug and gene are related, the drug suppressed the gene and the gene was implicated in the disease; it logically follows that the drug should be helpful in treating the disease.

Discussion

Our computational approach serves as a basis for new directions in drug repurposing, leveraging existing and commonly available bio-molecular phenotypic data. In order to validate our results, future laboratory-based testing will be conducted on a sub-set of our findings. The ability to link publicly available data sources is a central component of this work and emphasizes the importance of utilizing such data in conjunction with clinically-generated data sets so as to support in-silico hypothesis generation.

Conclusion

Utilizing publicly available data sets, we generated a list of 68,543 drug-gene-disease triplets, each triplet containing a gene that is up-regulated, a drug that works to suppress or inhibit that up-regulated function, and a disease where the up-regulated gene is an implicated disease agent. This information may play a significant role towards drug repurposing efforts in the 69 diseases. We anticipate that this information will prove useful to researchers in the domain of pharmaceutical drug repurposing and in the treatment of these conditions.

Rule-based Cervical Spine Defect Classification Using Medical Narratives

Yihan Deng[a], Mathias Jacob Groll[b], Kerstin Denecke[a]

[a] *Innovation Center of Computer Assisted Surgery, University of Leipzig, Germany*
[b] *Neurosurgical Department, University Hospital Leipzig, Germany*

Abstract

Classifying the defects occurring at the cervical spine provides the basis for surgical treatment planning and therapy recommendation. This process requires evidence from patient records. Further, the degree of a defect needs to be encoded in a standardized form to facilitate data exchange and multimodal interoperability. In this paper, a concept for automatic defect classification based on information extracted from textual data of patient records is presented. In a retrospective study, the classifier is applied to clinical documents and the classification results are evaluated.

Keywords:

Information Extraction; Cervical Vertebrae; Knowledge Bases.

Introduction

The degenerative changes of the cervical spine are reflected in multiple aspects of observation such as area of the defect, position of the defect and additional pathology. However, two challenges should be solved to enable the automatic defect classification in surgical context. Firstly, although the extraction of clinical evidence or disease characteristics from texts has been studied thoroughly using both rule-based or machine learning-based methods [1], the development of domain-specific extractor and classifier with high accuracy is still necessary for cervical spine diseases. Secondly, most of the available schemas for cervical spine defect classification focus on the pathological changes in the spinal canal or base on the cross-sectional area. A surgical classification schema must be implemented to provide surgeons with most essential defect situations.

Methods

In this paper, we employed a novel surgical oriented classification schema for the grading of spinal canal defects. It shows more defect information and categorizes additional pathological information for surgical practice use. It covers the amount of the affected cervical segments (Mono, Bi, Tri+, Skip Lesion), position of the defect (Medial (m), Lateral (l), Medial and Lateral (m&l)) and additional pathologies (Thickening of ligaments (1), disorders (listhesis, kyphosis, etc.) (2)). E.g., “bi-m2” refers to a bi-segmental stenosis with medial compression of the spinal cord with additional disorder.

A rule-based classification system based on extracted features are developed. As can be seen in figure 1, the information entities in medical narratives are extracted through concept mapper and regular expressions, while the classification schema is transformed into knowledge rules. As next, the rule based classifier determines the concrete defect classes for the patient record. Three hundred and eleven defect terms are categorized and summarized in the terminology manually. The relevant terms in the terminology list were directly linked to existing German terminologies such as Radlex, ICD 10 and MeSH 2010 as expansion. The defect relevant concepts, diagnoses and anatomical concepts are obtained through fuzzy matching and exact matching. The date, negation, measurement and dose in unit are also extracted. Fifty four facts and seven rules have been defined in our knowledge base using Prolog[1].

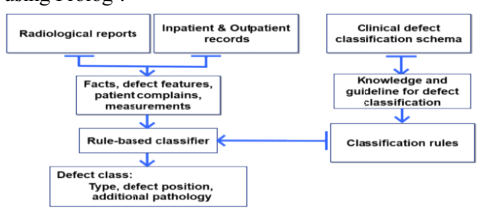

Figure 1- System flow chart of defect classification based on patient records

Results

One hundred samples of patient records in German were annotated with their defect features and classified defect codes as benchmarks by one physician. The extraction of the three defect features has reached high F1 measures ranging from 91% to 99%. The defect classification has also achieved generally high accuracy except for the detection of the position of “medial” (53%) due to an insufficient rule of facts in the knowledge base.

Conclusions

As a pilot study, preliminary experiments have been conducted with the support of surgeons. The usefulness of the automatic classification was confirmed by clinical experts. An additional clinical study will be organized for collecting more rule defintions from empirical experience. The rules will also be evaluted based on more patient record samples.

Comparing Drug-Disease Associations in Clinical Practice Guideline Recommendations and Drug Product Label Indications

Tiffany I. Leung, MD, MPH[a], Michel Dumontier, PhD[b]

[a]*Division of General Medical Disciplines, Stanford University, Stanford, CA*
[b]*Stanford Center for Biomedical Informatics Research, Stanford University, Stanford, CA*

Abstract

Clinical practice guidelines (CPGs) and structured product labels (SPLs) are both intended to promote evidence-based medical practices and guide clinicians' prescribing decisions. However, it is unclear how well CPG recommendations about pharmacologic therapies for certain diseases match SPL indications for recommended drugs. In this study, we use publicly available data and text mining methods to examine drug-disease associations in CPG recommendations and SPL treatment indications for 15 common chronic conditions. Preliminary results suggest that there is a mismatch between guideline-recommended pharmacologic therapies and SPL indications. Conflicting or inconsistent recommendations and indications may complicate clinical decision making and implementation or measurement of best practices.

Keywords:

Clinical Practice Guidelines; Drug Labeling; Drug Therapy; Information Storage and Retrieval; Chronic Disease.

Introduction

Clinical practice guidelines (CPGs) make recommendations on pharmacologic treatments for clinical conditions, and drugs' structured product labels (SPLs), provided by the U.S. Food and Drug Administration, summarize approved treatment indications. Both resources are intended to promote evidence-based medical practices and guide clinicians' prescribing decisions. Ideally, CPG and SPL content should support similar prescribing practices, reflecting a similar evidence base, however, no study has been done to evaluate how well these resources match. It is also labor-intensive to perform a manual review of the numerous existing CPGs and SPLs. In this study, we use text mining methods to examine how well CPG recommendations about pharmacologic treatment options for 15 common chronic conditions match with SPL treatment indications. We hypothesize that CPG recommendations and SPL treatment indications should be high.

Methods

We focused on 15 common chronic conditions among Medicare beneficiaries, using 448 ICD-9 codes to identify 494 relevant guideline summaries from the National Guideline Clearinghouse to build the CPG text corpus. To construct drug-disease associations from the CPG text corpus, we applied a text-mining algorithm that performs named entity recognition, similar to that used in a previous study to extract chronic disease mentions (1); however, we searched for drug names in the CPG text, using a drug list of over 12,000 drug names and synonyms from DrugBank, which we then enhanced with disease and drug vocabularies from Bioportal at Stanford's National Center for Biomedical Ontology. Then, we built drug-disease associations from SPLs' Indications section using a computer-readable side effect resource (SIDER). We measured the frequencies of matches and mismatches of drug-disease associations in CPGs and SPLs.

Results

We identified 1,998 unique drug-disease associations from CPGs; in SPLs, 533 unique drug-disease associations were identified. Of these, only 240 (45%) of these drug-disease associations matched between CPGs and SPLs. This means that CPGs mention 1,758 (88.0%) drug-disease associations that are not also mentioned in SPLs; conversely, SPLs mention 293 (55.0%) drug-disease associations that are not also mentioned in CPGs.

Conclusions

Our results suggest that there are mismatches between guideline-recommended pharmacologic therapies and SPL indications, suggesting potentially conflicting prescribing guidance from CPGs and SPLs. This can pose practical challenges for clinicians, patients and caregivers, and practice administrators. Further investigation of the identified mismatches may guide harmonization of clinical knowledge sources. In future work, improvement and evaluation of our text mining methods may address limitations of the present approach and extract relationship information between drug and disease.

Automated Classification of Pathology Reports

Michel Oleynik[a], Marcelo Finger[a], Diogo F. C. Patrão[b]

[a] *Institute of Mathematics and Statistics, University of São Paulo, São Paulo, Brazil*
[b] *International Center for Research, A. C. Camargo Cancer Center, São Paulo, Brazil*

Abstract

This work develops an automated classifier of pathology reports which infers the topography and the morphology classes of a tumor using codes from the International Classification of Diseases for Oncology (ICD-O). Data from 94,980 patients of the A.C. Camargo Cancer Center was used for training and validation of Naive Bayes classifiers, evaluated by the F_1-score. Measures greater than 74% in the topographic group and 61% in the morphologic group are reported. Our work provides a successful baseline for future research for the classification of medical documents written in Portuguese and in other domains.

Keywords:

Natural Language Processing; Medical Records; Data Mining.

Introduction

Pathology reports are an important data source for diagnosis in the cancer domain because reports provide clinical evidence on the topography of the tumor, its histological type, and morphology. The information may be encoded with the International Classification of Diseases for Oncology (ICD-O). A recent work [1] evaluated the use of Naive Bayes classifiers and Support Vector Machines, and we applied a modified version of these techniques on pathology reports written in Portuguese and assessed its efficiency.

Methods

We used a collection of pathology reports written in Portuguese from the A.C. Camargo Cancer Center in São Paulo, Brazil. The dataset comprises 94,980 patients from the years 1196 to 2010.

We applied a multinomial Naive Bayes classifier [2], seen in Figure 1, with add-alpha smoothing to the resulting data (we chose $\alpha = 0.5$ since our belief in uniformity is weak).

$$c_{map} = \underset{c \in C}{\operatorname{argmax}} [\log \hat{P}(c) + \sum_{1 \le k \le n_d} \log \hat{P}(t_k \mid c)]$$

Figure 1 – Naïve Bayes Classifier

Results

While one work [1] reported 71.5% F_1-measure on the classification of 26 topographic groups, we presented a higher F_1-measure (75.1%) on a task of 16 groups. On the morphology axis of the ICD-O classification, we achieved a lower F_1-measure (61.3% *versus* 85.4%) on a wider classification task (49 *versus* 18 groups). The results were micro-averaged with 10-fold cross-validation.

Table 1 – Micro-averaged efficiency (%) of Naive Bayes classifiers trained on increasing levels of detail of the ICD-O

	Topography			**Morphology**		
	P	**R**	**F_1**	**P**	**R**	**F_1**
Group	78.928	73.451	75.304	68.813	60.172	62.256
Category	73.180	69.284	69.284		N/A	
Concept	43.239	40.820	39.941	49.151	39.705	40.673

When analyzing the classifier efficiency on the topographic group, we achieved 98.3% and 97.3% precision on the groups *C50: Breast* and *C60-C63: Male genital organs*, respectively the most common cancer for women and men. We also analyzed the resulting confusion matrix and observed that the most common cause of error is the incorrect classification of *C50: Breast* as *C51-C58: Female genital organs*. This is probably due to the fact that the diagnosis of breast cancer is usually accompanied by a screening test for cervical cancer.

Conclusion

Our work has immediate implications to knowledge discovery and statistical analysis in the medical domain, as it eases the process of obtaining structured information over textual data. It also accelerates the work of physicians when classifying patient data.

Acknowledgments

This research was funded by the Brazilian National Research Council - CNPq (project number 133862/2010-0) and is approved by the committee on ethics on research of the A.C. Camargo Cancer Center (registered under number 1418/10).

Methods for Sonic Representation of ST Depression During Exercise

Minodora Andor[a], Anca Tudor[a], Sorin Paralescu[a], George I Mihalas[a,b]

[a] *Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*
[b] *Vasile Goldis Western University, Arad, Romania*

Abstract

Sonic display of ST depression during exercise helps both the patient and the investigator to better identify the transition from normal values to "attention" region and reaching the "alert" threshold. Two types of sonic display were tested, based on combinations of saccadic sounds and different pitch.

Keywords:

Sonification; ST depression; HR. alert threshold.

Introduction

This work is part of a larger project on "Adding Sound to Medical Data", to develop a toolkit for sonification of biological signals [1]. This study describes the module (ST) of the ASET package (Adding Sound to Exercise Test). Modern equipment displays the parameter evolution during exercise, underlying critical values of blood pressure (BP), heart rate (HR) and ST segment depression, each with well defined values as endpoints. The information is only visually displayed, the patient is kept passive. Our purpose was to improve the parameter perception and involve the patient.

Methods

Signals and Parameters

Signals. We used both our recordings and signals from Physiobank [2], from two leads (AVF or III and V5 or V6). The ST segment level was computed at the J point [3].

Thresholds. We used a simplified risk representation, preserving two major levels of warning, attention (close to risk threshold) and alert (endpoint), which are visually represented by a light red background of that parameter. The alert threshold STb = -1 mV in V5/V6 or STb = -1.5 mV in AVF/III , and the attention threshold was STa = 0.8 STb.

Sonification procedures

From the large selection of possible sonic representations, we have selected the following criteria: *duration* - equal to the RR interval for each beat, *pitch* - the reference frequency (f_0) was 523.25 Hz (C5 on musical scale), corresponding to ST_i < STb. For the three sounds displays, the next coefficients were ka=6/5; kb= 4/3, and *saccadic sounds.* We tried both continuous and saccadic sounds; a "saccade" was defined as a short sound (0.1 RR) followed by a pause of 0.02 RR. It can represent warning levels: 1 saccade for attention and three saccades for alert.Two types of sonic display were tried: saccadic sounds only ("1S") – no pitch variation (all C5), and saccadic display ("3S") of three sounds (C5/D5/E5): no saccade on f_0 - for normal range of HR, 1 saccade on $f_0 \times$ ka for attention level and 3 saccades on $f_0 \times$ kb for alert.

Preference selection

We conducted a survey with a group of 12 subjects. The survey had two phases: *supervised learnin*g - the subjects were exposed to the sounds and explained the two representations (named 1S and 3S), and *testing phase* - the subjects had to listen and score each record with marks between 10 and 0 (10 for perfect distinction). Each record was trimmed from the original 7-30 min. to 30–90 sec., preserving the transitions. The ASET package consists of two main scripts (in MATLAB 2011b) and several functions: ECG signal import into MATLAB, detection of RR intervals, detection of J point, ST value, and minimal ST level of the two leads. Then each signal was transformed for the two sonic representations (1S or 3S), using a function for saccades .

Results and Discussion

The sonic files used for testing with their graphical display and the corresponding sounds can be found on our website [4] in the section ASET. For stereo systems, HR sounds are sent to the right speaker while extra systoles are sent to the left.Our results (from 12 subjects, each for 5 signals) show that all sonic representations used in this study have very good discriminant power but different preference: the 1S display was not preferred when the 3S display was also available, but it can be kept in simple devices. From the comments made by the subjects we discovered preference to omit any sound before reaching the attention threshold and to introduce a dissonant note to mark the alert.

Conclusion

Our study showed a clear preference for simple displays (with no details), focused on revealing the threshold crossing. The potential impact of our study goes beyond the monitoring of cardiac performance during the exercise tests, to wearable devices with simple sonic warning system.

PIACS: A System for the Automatic Detection, Categorization and Comparison of Scratch-Related Skin Lesions in Dermatology

Philipp Bruland[a], Waldemar Hänse[a], Fiona Schedel[b], Sonja Ständer[b], Fleur Fritz[a]

[a] *Institute of Medical Informatics, University of Münster, Germany*
[b] *Department of Dermatology, University of Münster, Germany*

Abstract and Objective

In the treatment of chronic pruritus-related, scratch-induced skin lesions the categorization, counting and temporal comparison are common methodologies. The observation requires a good memory and expertise in this field to gain comparable findings for this time-consuming process. Digital image processing aims at supporting such manual detections. The objective is to develop a software tool for automatic image detection and comparison. The new photographic setting implies the usage of markers to derive the brightness and size of lesions. MATLAB has been used for the software development. The newly defined setting allows taking standardized images of pruritus-associated cutaneous lesions for detection and comparison. The tool named PIACS (Prurigo Image Analyzing and Comparing System) allows automatically detecting, categorizing and comparing lesions based on digital images.

Keywords:

Image processing; digital image detection; prurigo nodularis.

Introduction

The diagnostic and treatment of chronic pruritus becomes an increasingly important medical field in the dermatology. Besides common skin diseases, scratch-related skin lesions frequently occur in pruritus patients [1]. These lesions show a broad variability in redness, circularity as well as size and the also may serve as a monitor marker in the course of the therapy; however, they can only tediously be counted manually. Several hundred (mean, 180±146) of lesions are not uncommon. The manual process of classifying and counting is very time-consuming and not applicable in daily routine or clinical trials where a standardized procedure would be expedient [2].

Images are taken in a photographic laboratory but the photographic equipment has to be modified quite often. Flashes and lenses are changed, resulting in inconsistent brightness of the images. Automatic image detection is mainly applied for nevi and melanoma assessment for which images are taken [3]. The objective of this work is to develop a software tool to detect, classify and compare scratch-related skin lesions.

Methods

MATLAB was chosen for the development of since it offers the most comprehensive collection of image processing methodologies. For the three different lesions predefined parameters were applied for each category. Round gray markers were used to derive the real size in the image. The results of PIACS were evaluated by regarding correctness and accuracy of the detection within 25 randomly selected images.

Results

For the automatic detection of scratch lesions the following steps are performed: To extrapolate the skin and the marker in the image, it is separated into background, skin and the round marker. After that the marker is detected and the size derived for one pixel calculated in millimeter. The grey marker is used for color adjustment. Therefore, a reference image is prepared through the creation of red, green and blue histograms from 30 images. For the analyzed image the histogram adjustment is applied for each color channel. The detection of skin lesions is achieved by the subtraction of color channels and thresholding. The expanse and category is determined by the application of predefined parameters for each category. For the comparison two images are analyzed and the differences calculated.

On the 25 selected images in total 692 lesions were assigned. In total, 493 are correctly detected, 175 are categorized wrong and 24 are not detected. This results in an overall sensitivity of 95.7% and an accuracy of 75.3%.

Discussion / Conclusion

The examination process of pruritus-related scratch lesions may benefit from such an approach and is urgently needed for the application in diagnostic and treatment as well as clinical trials to allow proper and objective assessment of the course of the symptom. The accuracy might be improved through the introduction of artificial neural networks.

The MFER structure for coding medical signals in real time

Yonghee Lee[a], Jaehyuk Kim[a], Soonseok Kim[a], Kangwoo Lee[a], Dongho Kim[a]

[a] *Department of Computer Engineering, Halla University, Wonju, Korea*

Abstract

We present the structure of the MFER coder to store the medical signals in real time. The MFER is the rules to describe the file with tags the medical signal such as ECG, EEG, etc. However, because the MFER has the simple structure, and is stored as a file unit, it is difficult to process the signal with MFER rules in real-time. To do this, By storing the signal into small unit of time, it is possible to handle as if the signal is stored continuously. The structure of the presented MFER coder is verified in the results.

Keywords:
medical waveform, MDER, healthcare, MFER

Introduction

The MFER (Medical Waveform Format Encoding Rules) is a set of rules to store the medical waveforms such as ECG, EMG, EEG, etc., its rules basically consist of the tag (T), the length (L), and length of data value (V) based on MDER. And, the value (V) represents data indicated by the tag (T). To describe a signal, the MFER consists of the sampling attribute, frame attribute, and supplementary information. The file data is fundamentally composed of a header and waveform data of the signal, and the header and waveform data are encoded after dividing them into a tag, length, and value. However, even though the MFER has the simple structure so that we are able to deal with them, easily, the structure does not support real-time process. It is very important to store and monitor the waveform of a patient in real time from a remote location over the network. In this paper, we propose the coding structure to monitor in real-time based on the basic MFER.

Materials and Methods

The coding structure

Figure 1 shows the structure of the proposed MFER coder. First, We send the header block containing the waveform information before transmitting the continuous wave from the device to the server. This process will automatically transfer from the medical device, or enter manually in server system. Then, the medical device send a continuous waveform, and the server is attached to a block of the header information by dividing the waveform signal into block units. We are able to deal with, such as if subsequently store and monitor the waveform information when the monitoring result from the server side. Figure 2 describes how to design the corresponding tag. This interface could make quite good use when tags are called or discriminated in a linked list later.

Adding Sound to ECG

George I Mihalas[a,b], Sorin Paralescu[a], Anca Tudor[a], Minodora Andor[a]

[a] *Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*
[b] *Vasile Goldis Western University, Arad, Romania*

Abstract

This poster presents preliminary results of a project aiming to develop tools for adding sound associated to medical data for potential medical applications. Sonification procedures, the methodology used for testing various sonic representations of ECG, and the results are presented.

Keywords:

Sonification; Data representation; ECG; Discriminant power.

Introduction

The use of sonification for representation of medical data, especially biosignals is not a new idea [1], but most previous work has limited approaches. A systematic study has yet to be completed, due to the diversity of methods to "sonify" a set of data. From this premise, we initiated a project: “Adding Sound to Medical Data”, with four steps [2]:

- preparing the sonification tools and methodology;
- testing the discriminant power of various sets of parameters;
- developing the procedure for clinical application;
- development of sonification modules for medical equipment.

This paper refers only to the first two phases.

Methods

The first stage aimed to reduce the degree of arbitration in mapping the physical parameters of the original signal (data).

Sonification procedures

In our approach [3], the relation between the sound pitch (f_i) and normalized data [0,1] of signal amplitude y_i was:

$$f_i = f_0 \times 2 \text{ ^ } (y_i),\ f_0 = 523.25 \text{ Hz (note C5)} \quad (1)$$

Three major sonification levels could be defined:

- acoustic level, with a continuous frequency spectrum (f);
- sonic level (S) – with discrete spectrum, from musical scale;
- musical level (M) – multichannel, introducing rhythm and harmony. Level M will not be referred to in this paper.

We split the acoustic level into two (sub)levels:

- *continuous* representation, called (sub)level (A): for two neighbor points (t_i, f_i) and (t_{i+1}, f_{i+1}), the frequency will vary continuously from f_i to f_{i+1};
- *quasicontinuous* (sub)level (Q) representation: only the frequency f_i will be produced for the interval dt = (t_i, t_{i+1}), followed by f_{i+1} for the next interval dt , etc.

We used signals from PhysioBank [3] (sampling rate 250 Hz) from both healthy subjects and from patients with sleep apnea, arrhythmia and congestive heart failure. Additionally, we built a tool similar to a lens - tempolens, (TL) able to dilate or compress temporal sonic display, with fixed (f) or variable (v) magnification [2].

Results and Discussions

Computer programs

Our package was built on MATLAB R2011b platform, for sonifying a signal in levels A, Q and S and applying tempolenses. An example of the screen produced for an ECG signal of 10 seconds and the sounds can be displayed by accessing reference [4].

Discriminant power

We tested the discriminant power (the capacity of listeners to distinguish details and recognize signals). Our results showed:

- low preference for A mode (it sounds like a whistle), but had a high discrimination in sleep apnea (obstructive episodes);
- tempolenses with variable magnification did not bring the expected increase in resolution of the QRS complex;
- durations of 0.2 seconds or less in Q mode sounded like A.

Conclusions

We built and tested a methodology for adding sound to medical data to improve data analysis in various cases: HR variability recognition, differential diagnosis, exercise tests, help people with visual impairment, etc.

An Optimized Superpixel Clustering Approach for High-Resolution Chest CT Image Segmentation

Rafaelo Pinheiro da Rosa[a], Marcos Cordeiro d'Ornellas[a]

[a] *Laboratório de Computação Aplicada, Universidade Federal de Santa Maria, Santa Maria-RS, Brasil*

Abstract

Lung segmentation is a fundamental step in many image analysis applications for lung diseases and abnormalities in thoracic computed tomography (CT). However, due to the large variations in pathology that may be present in thoracic CT images, it is difficult to extract the lung regions accurately. A major insight to deal with this problem is the existence of new approaches to cope with quality and performance. This poster presents an optimized superpixel clustering approach for high-resolution chest CT segmentation. The proposed algorithm is compared against some super-pixel algorithms while a performance evaluation is carried out in terms of boundary recall and under-segmentation error metrics. The over-segmentation results on a CT Emphysema Database demonstrate that our approach shows better performance than other three state-of-the-art superpixel methods.

Keywords:

Image Segmentation; Radiography Image Interpretation; Tomography.

Introduction

Medical imaging is now used to provide interventional treatments and diagnostic screening. It allows for substantial information about abnormal adjacent tissues, helping physicians to identify the appropriate treatment. Recently, superpixels have converted into an essential approach for many imaging applications including segmentation [1]. This poster presents an optimized superpixel clustering approach for high-resolution chest CT segmentation. The proposed algorithm is compared against some superpixel algorithms while a performance evaluation is carried out in terms of boundary recall and under-segmentation error metrics.

Methodology

The algorithm presented in this poster is an optimized version of the original SLIC algorithm [2], with some differences. A performance evaluation of the ESLIC algorithm was exhibited by comparing its accuracy against SLIC, NC00, QS08, and TP09 algorithm. The ESLIC algorithm was implemented in Java. While only comparisons with original algorithms and extensions have been made, computer benchmarks were performed in C using a commodity computer.

Results

Figure 1 in the left shows the results obtained with under-segmentation error metric. It can be concluded from this plot that ESLIC exceeds the other algorithms after 900 superpixels. In the right, results for boundary recall are displayed. In this plot, ESLIC exceeds QS08 and TP09. It is also higher than NC00 when 50 superpixels are considered. Figure 2 shows a visual comparison, produced by each one of the algorithms considered in this work.

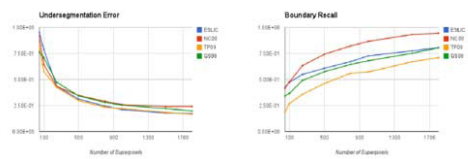

Figure 1 – Plot of USE (left) and BR(right) with respect to number of superpixels.

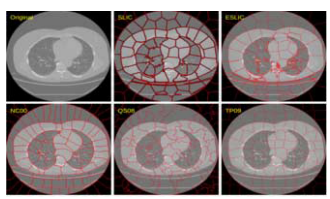

Figure 2 – Segmentation results on CT sample for SLIC12, ESLIC, NC00, QS08, and TP09.

Conclusion and Further Work

In this poster, NC00, QS08, TP09, and SLIC12 algorithms were compared against ESLIC. Results have shown that the proposed algorithm is superior, with respect to under-segmentation error, to the other algorithms. When considering boundary recall, ESLIC performs better than QS09 and TP09 but is outperformed by NC00.

Automated Image Retrieval of Chest CT Images Based on Local Grey Scale Invariant Features

Marcelo Arrais Porto[a], Marcos Cordeiro d'Ornellas[b]

[a] *Animati Computação Aplicada, Santa Maria-RS, Brasil*
[b] *Universidade Federal de Santa Maria, Universidade Federal de Santa Maria, Santa Maria-RS, Brasil*

Abstract

Textual-based tools are regularly employed to retrieve medical images for reading and interpretation using current retrieval Picture Archiving and Communication Systems (PACS) but pose some drawbacks. All-purpose content-based image retrieval (CBIR) systems are limited when dealing with medical images and do not fit well into PACS workflow and clinical practice. This paper presents an automated image retrieval approach for chest CT images based local grey scale invariant features from a local database. Performance was measured in terms of precision and recall, average retrieval precision (ARP), and average retrieval rate (ARR). Preliminary results have shown the effectiveness of the proposed approach. The prototype is also a useful tool for radiology research and education, providing valuable information to the medical and broader healthcare community.

Keywords:

PACS; Image Retrieval; Chest CT Images; Local Features.

Introduction

Medical imaging has become essential for modern medicine. However, image interpretation and understanding poses a significant and continuous burden on physicians who need to evaluate large amounts of data. In order to tackle these challenges, a generic integration of computer-aided diagnosis (CAD) and content-based image retrieval (CBIR) is proposed. CBIR usually employs a set of low-level feature descriptors to represent a medical image, from which a group of similarity functions are used to drive different sorts of queries. This helps physicians to find similar cases from a variety of archives, thus providing support with medical image interpretation and decision-making.

This paper presents an automatic approach to image retrieval of chest CT images based on local grey scale invariant features such as scale-invariant feature transform and multi-scale oriented patches.

Methods

Feature vectors, obtained by low level features, are fundamental to assess similarity measurements in CBIR searching process. Feature extraction methods must be stable and robust to enable image recognition and retrieval. Local invariant methods have been employed to tackle these problems including SIFT and MOPS[1]. We adopt MOPS algorithm in this paper for feature extraction and matching of chest CT images. MOPS is a relatively lightweight scale invariant feature detector compared to SIFT, and has advantage of faster detection speed.

Results

A MOPS implementation was tested using three different public domain training datasets (CTED[2], TCGA-LUSC, and NSCLC-Radiomics) to validate its efficiency. The algorithm ranks the images in descending order of the maximum region similarity. The top ranked images are taken as the candidate retrieval results.

The retrieval performance of the proposed method is measured in terms of recall, precision[*], average retrieval rate (ARP) and average retrieval precision (ARR). Figures 1 illustrates the retrieval performance comparison of the proposed approach for all datasets in terms of ARP and ARR.

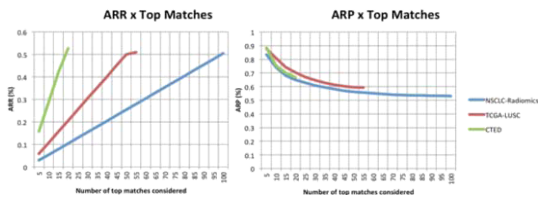

Figure 1 – ARPxTop (left) and ARRxTop (right) matches for all datasets.

Conclusion and Further Work

The goal of this paper was to provide an automated chest CT image retrieval approach based on local grey scale invariant features. To access the correctness of query results, an evaluation procedure was carried out in terms of PR plots, average retrieval precision and average retrieval rate. The proposed approach is still not optimal and performance considerations must be taken into account in the near future.

Texture Analysis of Recurrence Plots Based on Wavelets and PSO for Laryngeal Pathologies Detection

Taciana A. Souza [a], Vinícius J. D.Vieira[b], Suzete E. N. Correia[a], Silvana L. N. C. Costa[a], Washington. C. de A. Costa[a], Micael A. Souza[a]

[a]Academic Unity of Industry, Electrical Engineering, IFPB, João Pessoa, Brazil
[b]Electrical Engineering Post-graduation Program, UFCG, Campina Grande, Brazil

Abstract

This paper deals with the discrimination between healthy and pathological speech signals using recurrence plots and wavelet transform with texture features. Approximation and detail coefficients are obtained from the recurrence plots using Haar wavelet transform, considering one decomposition level. The considered laryngeal pathologies are: paralysis, Reinke's edema and nodules. Accuracy rates above 86% were obtained by means of the employed method.

Keywords:

Wavelet Transform; Haralick Features; Recurrence Plots; Laryngeal Pathologies.

Introduction

Laryngeal pathologies might affect the speech production process. Recurrence plots have been used in the discrimination of healthy and pathological speech signals recently [1]. These structures show small scale patterns (which can be seen as texture features) and large scale patterns (which can be seen as typology features) [2].

This research employs Haralicktexture analysis features [3] on coefficients obtained from sub-images of the wavelet transform [4] applied in recurrence plots of speech signals. The discriminative power among pathologies in the larynx is investigated through the inspection of the visual information in the recurrence plots. Three pathologies are considered for analysis: paralysis, Reinke's edema and nodules.

Methods

Approximation and detail coefficients are obtained from the recurrence plots using Haar wavelet transform, considering one decomposition level. The texture analysis is carried out with Haralick features on these coefficients. The speech signals are classified by multilayer perceptron neural network (MLP) with cross validation. The most significative features are selected by particle swarm optimization (PSO) [5]. This classification step is carried out for each coefficient matrix (approximation, horizontal, vertical and diagonal details).

The speech signals used in this research belong to a database recorded by the Massachusetts Eye and Ear Infirmary (MEEI) Voice and Speech Lab [6]. The use of 53 signals of healthy larynx, 51 signals of paralysis, 43 signals of Reinke's edema, and 18 signals of nodules is taken into account.

Results

The classification performance for the selected features is shown in Table 1. The accuracy refers to the correctly classified cases, including all analyzed signals. The specificity means the correct classification of health cases (true negative) and the sensitivity corresponds to the pathological voices correctly classified (true positive).

Table1– Classification performance obtained withPSO algorithm and MLP.

Classification Cases	Accuracy (%)	Specificity (%)	Sensitivity (%)
HTYxPTL	88±5	87±4	63±10
HTYxPRL	91±4	74±9	93±5
HTLxEDM	86±4	62±8	88±4
HTYxNDL	91±3	50±10	96±2

Conclusion

The use of wavelet transform and Haralick features may be considered as an applicable tool to texture analysis of recurrence plots in order to identify laryngeal pathologies. For validating the technique, practical tests are necessary.

On The Correlation Between Geo-Referenced Clinical Data And Remotely Sensed Air Pollution Maps

Arianna Dagliati[a], Andrea Marinoni[b], Carlo Cerra[c], Paolo Gamba[b], Riccardo Bellazzi[a]

[a] *Laboratory for Biomedical Informatics, University of Pavia, Italy*
[b] *Telecommunications and Remote Sensing Laboratory, University of Pavia, Italy*
[c] *Department of Purchasing and Control, ASL Pavia, Italy*

Abstract

This work presents an analysis framework enabling the integration of a clinical-administrative dataset of Type 2 Diabetes (T2D) patients with environmental information derived from air quality maps acquired from remote sensing data. The research has been performed within the EU project MOSAIC, which gathers T2D patients' data coming from Fondazione S.Maugeri (FSM) hospital and the Pavia local health care agency (ASL). The proposed analysis is aimed to highlight the complexity of the domain, showing the different perspectives that can be adopted when applying a data-driven approach to large variety of temporal, geo-localized data. We investigated a set of 899 patients, located in the Pavia area, and detected several patterns depicting how clinical facts and air pollution variations may be related.

Keywords:

Geo-referenced data; Environmental factors; Type 2 Diabetes; Air pollution maps.

Introduction

The environment's involvement in health issues has been defined as the Exposome [1]. One of the main advantages of the available data sets is that, thanks to the information derived from the local healthcare agency, patients' addresses are associated to municipality codes. Precisely locating patients enables the investigation of their interactions with the territory. It has also been stated that the combination of wide-ranging data sources requires innovative analysis approaches from methods and data management point of view [2]. In our case a further step in the study was triggered by merging biomedical informatics with telecommunications and remote sensing domain expertise. We exploited geo-referenced clinical data to understand the effects of being exposed with air pollutants thanks to air quality maps acquired from remotely sensed data.

Materials and Methods

The joint analysis of air quality maps and geo-localized clinical events gave the possibility to observe multiple patterns varying over time. Comparing these trends provided some insight about the evolution of severe events, which are those requiring hospitalization.

In order to achieve air quality maps, the data acquired by Landsat L8 mission have been considered. Landsat 8 satellite was launched in February of 2013. The satellite collects images of the Earth with a 16-day repeat cycle, referenced to the Worldwide Reference System-2. Thanks to the assumption that pollution plays a key-role in the thermal pattern of a remotely sensed scene [3], the correlation between the presence of black particulate and the recorded temperature can be thoroughly characterized. In order to match the region of the remotely sensed data with the Pavia area, we implemented spectral analysis taking into account the overall pattern of the raw counts thermal signal as a function of black particulate concentration. For each pixel in every temporal series, a polynomial fitting model has been implemented to estimate the air quality of the scene [3]. Air quality has been quantized on five levels over the black particulate concentration estimate.

While observing that, during the analyzed time window, the number of hospitalizations in two considered areas follows inverse trend during the coldest season, we were able to describing those events per-se. Although, thanks to additional source of data, we can also infer that there are other external factors entailing the observed facts, so to enable the discovery of additional explanations of clinical phenomenon.

Results

Through the information acquired from air-quality maps we observed that, in different areas, the increased number of hospitalization was related to different value of air pollutants. In particular we focused on the area named Lomellina during the February month. In this period in-hospital events account for the 31.58% of the entire observations, which is the highest value compared with other areas; within the same time window and area it was possible to detect worsened condition from air quality maps (Particulate Matter values increased from 51/71 mg/m^3 in December to 76/100 mg/m^3 in February).

Conclusions

Merging heterogeneous information coming from various scientific disciplines is the trigger to inspect complex evolution patterns of diseases. Our findings provided meaningful hints to investigate further how clinical acute events may be explained by exogenous factors.

Integrating data from multiple sources for data completeness in a web-based registry for pediatric renal transplantation - the CERTAIN Registry

Lennart Köster[a], Kai Krupka[b], Britta Höcker[b], Axel Rahmel[ce], Undine Samuel[c], Wouter Zanen[c], Gerhard Opelz[d], Caner Süsal[d], Bernd Döhler[d], Lukasz Plotnicki[b], Christian D. Kohl[a], Petra Knaup[a], Burkhard Tönshoff[b]

[c] *Stichting Eurotransplant International Foundation, Leiden, The Netherlands*
[d] *Department of Transplantation Immunology, University Hospital of Heidelberg, Germany*
[e] *German Organ Transplantation Foundation, Frankfurt, Germany*

Abstract

Patient registries are a useful tool to measure outcomes and compare the effectiveness of therapies in a specific patient population. High data quality and completeness are therefore advantageous for registry analysis. Data integration from multiple sources may increase completeness of the data. The pediatric renal transplantation registry CERTAIN identified Eurotransplant (ET) and the Collaborative Transplant Study (CTS) as possible partners for data exchange. Import and export interfaces with CTS and ET were implemented. All parties reached their projected goals and benefit from the exchange.

Keywords:

Patient registry; data integration; interfaces; pediatric-kidney transplantation.

Introduction

Patient registries collect data about the patients' course of disease or therapy. Registries rely on good data quality and completeness as the observations made from the available data only pertain to the observed population and are not generalizable [1]. To increase data completeness, the pediatric renal transplantation registry CERTAIN [2] decided to exchange data with ET and CTS to increase data completeness.

Materials and Methods

The CERTAIN Registry is an in-house developed registry written in Java with a web-client based on Google Web Toolkit and an SQL database. Interfaces with other data sources and organizations are implemented in-house. Currently 51 centers from 10 countries contribute to the registry.

Results

Import of data from CTS provided CERTAIN with new patients and long-term follow-up data. Export to CTS prevents double-entry of CERTAIN-data into CTS. High quality donor and recipient data could be obtained through the continuous data exchange with ET. Exporting follow-up data to ET provides a larger data basis for future evidence-based improvement of organ allocation. Up to now, data from 285 patients have been imported from CTS. ET has received follow-up data for 1096 visits of 193 patients. CERTAIN received notification of 436 transplantations from ET.

Discussion

Establishing exchanges with ET and CTS was a major step towards data completeness while easing data entry for participating centres. Interface-implementation required considerable coordination and effort from all parties. Privacy concerns proved to be the biggest challenge to be solved. Reconciliation of data sets proved to be time-consuming.

Conclusion

We established the communication and data exchange of the CERTAIN Registry with CTS and ET respectively. Both interfaces increased the completeness of CERTAIN's data set. The data exchange has proven to be beneficiary for the CERTAIN Registry and the participating organizations. Data exchange with other registries may further benefit all parties.

Development of Unified Lab Test Result Master for Multiple Facilities

Naoto Kume[a], Kenji Suzuki[b], Shinji Kobayashi[a], Kenji Araki[c] and Hiroyuki Yoshihara[c]

[a] EHR research unit, Kyoto University, [b] SRL Inc, [c] Miyazaki University Hospital

Abstract

A clinical study requires massive amounts of of lab test data, especially for rare diseases. Before creating a protocol, the hypothesis if the protocol will work with enough amount of patients' dataset has to be proved. However, a single facility, such as a university hospital, often faces a lack of number of patients for specific target diseases. Even if collecting datasets from several facilities, there is no active master table that can merge lab test results between the facility datasets. Therefore, the authors develop a unified lab test result master. Because test master standards such as JLAC10 and LOINC are provided from a viewpoint of academic classification of laboratory medicine, the classification does not fit clinical classification, which doctors understand with a mind-set of establishing a clinical study protocol. The authors establish a method to unify masters using an active lab test result master from two university hospitals.

Keywords:

EHR; Lab test master; JLAC10.

Introduction

For developing a clinical study protocol, the expected number of patients is important to decide if the study is actually carried out. In a single facility, such as a university hospital, it is difficult to assume how many patients are in a region. Therefore, researchers have to assume a high burden for case finding by communicating with multiple facilities. Even if all test results are provided from participant facilities, merging results is another huge burden before analysis. Therefore, a unified lab test master is required to compare datasets between different facilities.

Beforehand, the authors tried to use a standard master JLAC10, which is provided by the Japanese Society of Laboratory Medicine. The results reflect that the master is classified from a viewpoint of academic classification of lab tests so that it was difficult to merge test results between facilitites. At the trial, four university hospital's masters, with about three to five thousand lines, are matched. Only a hundred items can be described by the unified master.

Therefore, the authors propose a master table merging method to establish a unified master from a viewpoint of a doctor's mind, which is adopted when a clinical study is designed.

Methods

To decrease the burden of master table matching, the methods proceeds with three steps. Eventually, the proposed unified master code consists of a combination of high-order digits and two original sub-codes. For the first step, an actual lab test result dataset is analyzed to select active items. Since an active lab test master is always maintained in each facility, some items are active and some are not. Two years lab test results provide active test items, traditional items, and inactive items. For the second step, an accounting information table and a test order item table are provided. The test order item contains in many cases multiple test result items. In some cases, order items contains a single test result item. Therefore, a unified master code high-order number is given by an accounting information table code, which is provided by the Ministry of Health, Labour and Welfare in Japan. Since in Japan the accounting code is unified, every facility has the same code. The rough classification of lab result items has been analyzed with the accounting code. Figure 1 depicts the unified master code construction.

For the third step, matchings of each item from unified code and facility code are analyzed by manually checking item names. Sub-code 1 classifies specimen and dose amount. Sub-code 2 classifies details such as methods, units and applied standards.

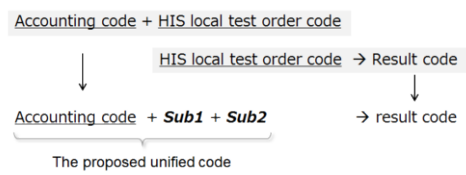

Figure 1. Unified code structure

Results

A beta version of a unified code is generated by two university master codes. The total amount of unified codes covers around 800 result items. Some original facility tests and subcontract lab test results are not yet stored in the unified code.

Conclusion

A unified lab test result master is proposed for clinical study case findings. The combination code of accounting code and sub-classification code provides the unified master code.

Semantic Web Ontology and Data Integration: a Case Study in Aiding Psychiatric Drug Repurposing

Chen Liang, Jingchun Sun, Cui Tao

School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX, USA

Abstract

There remain significant difficulties selecting probable candidate drugs from existing databases. We describe an ontology-oriented approach to represent the nexus between genes, drugs, phenotypes, symptoms, and diseases from multiple information sources. We also report a case study in which we attempted to explore candidate drugs effective for bipolar disorder and epilepsy. We constructed an ontology incorporating knowledge between the two diseases and performed semantic reasoning tasks with the ontology. The results suggested 48 candidate drugs that hold promise for further breakthrough. The evaluation demonstrated the validity our approach. Our approach prioritizes the candidate drugs that have potential associations among genes, phenotypes and symptoms, and thus facilitates the data integration and drug repurposing in psychiatric disorders.

Keywords:

Drug Repurposing; Ontology; Data Integration.

Introduction

Despite the remarkable progress in fundamental research and medications, efforts toward the discovery of new drugs for psychiatric disorders have been relatively unsuccessful compared to drug discovery for other diseases. There is an imperative for discovering novel solutions. Researchers have attempted to develop new solutions including drug repurposing [1], which aims to develop new uses for existing or abandoned drugs [2]. Drug repurposing methods encompass a wide spectrum ranging from traditional screening methods and animal models to computational methods [3]. Computational methods hold promise for facilitating the identification of candidate drugs with the advantage of time efficiency. We proposed a framework built under the W3C Standard of Web Ontology Language (OWL). We also described a use case with a semantic reasoning task using the ontology to explore candidate drugs activating for bipolar disorder and epilepsy.

Methods

We defined five top-level classes (disease, symptom, phenotype, gene, and drug), along with the corresponding OWL object properties to represent the metaontology. The detailed ontology includes OWL individuals that were defined under the corresponding classes to model real-world entities. In our ontology, these instances were imported primarily from open data repositories, including PharmGKB, Human Phenotype Ontology, and Online Mendelian Inheritance in Man. We encoded symptom-associated information for the ontology since there is no existing data repository providing such information. In the use case, we generated Descriptive Logic (DL) Rules for delivering reasoning results. For example, one DL rule to find a new path between drugs and diseases can be defined as *"DrugRelatedToGene some (associatedWithPhenotype some (associatedWithSymptom some ((associatedWithDisease some Bipolar_disorder) and (associatedWithDisease some Epilepsy))))"*. A candidate drug inferred by this DL must be a drug that associates with symptoms that appear in Bipolar_disorder and Epilepsy. The associations between drug and symptom were inferred through drug-gene-phenotype-symptom. To validate the inferred candidate drugs and ontology effectiveness, we used data from PharmGKB, ClinicalTrial.gov, and PubMed for the evaluation.

Results

The ontology inferred 48 drugs relevant to the two diseases. We further evaluated whether symptoms contain important information in guiding drug selection. The result shows that one out of the 48 drugs has direct disease-gene-drug associations. Eleven drugs have been investigated in the clinical trials on both bipolar disorder and epilepsy. Eighteen drugs from our queried results that revealed joint occurrences of the drug name and the two disease names in PubMed, among which only four drugs revealed weak evidence (returned the occurrence of one). Eleven drugs were identified from both ClinicalTrial.org and PubMed.

Personalised Medicine Possible With Real-Time Integration of Genomic and Clinical Data To Inform Clinical Decision-Making

Fernando Martin-Sanchez[a], Maureen Turner[a], Alice Johnstone[a], Leon Heffer[a], Naomi Rafael[a], Advisory Group[b], Tim Bakker[b], Natalie Thorne[b], Ivan Macciocca[b], Clara Gaff[b]

[a] *BioGrid Australia, Melbourne, VIC, AUSTRALIA*
[b] *Melbourne Genomics Health Alliance, Walter and Eliza Hall Institute of Medical Research, Melbourne, VIC, AUSTRALIA*

Abstract

Despite widespread use of genomic sequencing in research, there are gaps in our understanding of the performance and provision of genomic sequencing in clinical practice. The Melbourne Genomics Health Alliance (the Alliance), has been established to determine the feasibility, performance and impact of using genomic sequencing as a diagnostic tool.

The Alliance has partnered with BioGrid Australia to enable the linkage of genomic sequencing, clinical treatment and outcome data for this project.

This integrated dataset of genetic, clinical and patient sourced information will be used by the Alliance to evaluate the potential diagnostic value of genomic sequencing in routine clinical practice. This project will allow the Alliance to provide recommendations to facilitate the integration of genomic sequencing into clinical practice to enable personalised disease treatment.

Keywords:

Translational Medical Research; Process Assessment (Health Care); Data Linkage; Genomics; Individualized Medicine.

Introduction

Over 14,000 genes are known to cause or contribute to disease [1] and over 2,000 diagnostic genetic tests are now available in clinical practice [2]. Despite widespread use of genomic sequencing in research, there are gaps in our understanding of the performance and provision of genomic sequencing for clinical use. The Melbourne Genomics Health Alliance (the "Alliance") was launched as a collaboration between seven Melbourne-based research and clinical organisations. The Alliance has been established to determine the feasibility, performance and impact of using genomic sequencing as a diagnostic tool with the objective of demonstrating that personalised medicine through targeted genomic analysis is possible.

Methods

To enable the linkage of genomic sequencing, clinical treatment and outcome data, the Alliance has partnered with BioGrid Australia for this project. BioGrid Australia operates a secure federated data-sharing platform that enables real-time integration of record-level data across institutions and jurisdictions. This platform provides ethical access to data while protecting both privacy of the participants and the intellectual property of the contributing organizations. Importantly, the platform has the capability to provide an integrated view for the treating clinician as well as project wide reporting.

Results

This project has created a unique integrated dataset of diverse genetic, clinical and patient survey information to evaluate the potential diagnostic value of genomic sequencing in routine clinical practice. As the project continues into its next phase, the Alliance will build on these initial results to gain a better understanding of the process requirements to use genomic sequence data in clinical care.

Discussion

As the use of genomic sequencing information in clinical care is limited, the Alliance has created a novel way to facilitate the integration of genomic sequencing into clinical practice. The results of the demonstration project will be used by the Alliance to provide process recommendations for subsequent implementation to improve both the impact and the performance of genomic sequence information in clinical practice and personalised care.

Conclusion

These translational analyses provide the groundwork for identifying the processes required for further exploration of targeted personalised disease treatment in clinical practice.

Integration of Disease Specific Clinical and Genomics Datasets using I2B2 Framework

Mohyuddin[a]

[a] *King Abdullah International Medical Research Center (KAIMRC), National Guard Health Affairs (NGHA), Riyadh, Saudi Arabia.*

Abstract

The availability of a patient's genomic profile along with the clinical profile for providing individualized care and treatment is paving the road for a new era of personalized medicine, and is an important area of focus in current biomedical research. One of the prominent and globally implemented solutions for clinical and genomics data integration in biomedical research is an NIH funded NCBC initiative - Informatics for Integrating Biology and the Beside (I2B2). This paper presents the development of a pilot prototype for integrating patient's clinical and genomics datasets using open source and scalable I2B2 Framework. It focuses on disease specific clinical data and genomic variants, when combined together can be used for informed decision making in clinical practices by healthcare professionals and for further investigations by biomedical researchers. The research was carried out using a case study of King Abdullah International Medical Research Center (KAIMRC) in collaboration with King Fahad National Guard Hospital (KFNGH).

Keywords:

Integrated Health Care Systems; Cohort Analysis; Information Retrieval; Dataset; Biomedical Research

Introduction

Since the completion of Human Genome Project, biomedical literature has shown abundance of various approaches for data integration, such as federated databases, data warehouses and data management systems; but most of them focus only on genomics data integration from heterogeneous resources [1, 2]. I2B2 provides an environment where users can perform queries and cohort analysis by integrating clinical and biomedical data together, that can be used for discovery research and targeted therapies for individual patients having genetic diseases [3]. For the proof of concept, we developed a pilot prototype to evaluate feasibility of using I2B2 for integrating anonymized patients' clinical and genomics datasets.

Methods

The sample clinical dataset included patients' demographics and basic disease profiles, such as gender and age information, disease type, stage and level. The sample genomic variations data, prepared by studying DECIPHER project [4], included number of genes, inheritance levels and variant locations containing chromosome number, start location and end location. Both datasets were further customized for mapping and interoperability with I2B2 star schema and ontology.

Results

I2B2 data warehouse (hosting our clinical and genomics datasets) and data management services (core server-side cells - the hive and client-side applications - web client and workbench) were installed and configured in Windows and Linux Platforms. In Windows, we deployed I2B2 image using virtualization software - VMware Player; whereas in Linux - we used terminal along with I2B2 Wizard [5] to install and configure the requisite I2B2 softwares. After datasets' customization, IDRT Import Tool [5] was used for importing both datasets in I2B2 data warehouse. Finally, the web client was used for data query, cohort analysis and information visualization.

Figure 1-Clinical and Genomics Data Integration using I2B2

Conclusion

We found that I2B2 installation, configuration and data import process is complex, and also multiple data formats support is limited. The successful implementation of current pilot prototype has laid foundations of our future work where we will target the integration of local patients' disease and genetic registries based on stakeholders' requirements using I2B2.

Bridging the Gap from Bench to Bedside – An Informatics Infrastructure for Integrating Clinical, Genomics and Environmental Data (ICGED)

Mohyuddin

King Abdullah International Medical Research Center (KAIMRC), National Guard Health Affairs (NGHA), Riyadh, Saudi Arabia.

Abstract

The abundance of heterogeneous biomedical data from a variety of sources demands the development of strategies to address data integration and management issues, so that the data can be used effectively in clinical practices and biomedical research. This research presents an Informatics Infrastructure for Integrating Clinical, Genomics and Environmental Data (ICGED) and provides a roadmap that envisions utilizing the clinical and biomedical resources in our case study. This work describes a data integration approach, proposed by ICGED, with a two-fold purpose: personalized medicine and biomedical data storage and sharing platform. It describes our experiences integrating disease specific clinical and genomics datasets with Data Integration and Analysis Tools (DIAT)—using Informatics for Integrating Biology and the Bedside, and discusses work in progress and future work for extending DIAT, and the development of Risk Assessment and Prediction Tools, Clinical Decision Support Systems and a Bioinformatics Data Warehouse.

Keywords:

Personalized Medicine; Integrated Health Care Systems; Information Sharing; Risk Assessment; Decision Making.

Introduction

Personalized Medicine provides individualized treatment based upon a patient's unique clinical, genomic and environmental profile, and likelihood to a drug/therapy response, by using precise risk assessment and clinical decision support tools [1]. This research investigates the development and utilization of such tools in the resource structure of our case study of the King Abdullah International Medical Research Center and the King Fahad National Guard Hospital. Initial requirements analysis showed a need for using translational research and biomedical data infrastructure.

Methods

This research proposes an Informatics Infrastructure for Integrating Patient's Clinical, Genomics and Environmental Data (ICGED), which provides a centralized platform for data deposition and analytics, information access and sharing, and knowledge extraction. This platform will allow healthcare staff to find relevant information for individualized patient treatment, and biomedical researchers to utilize existing information for further research. Figure 1 shows the ICGED roadmap for our on-going and future research work.

Figure 1 – ICGED Roadmap

Results

For proof of concept, a pilot prototype was developed as a part of Data Integration and Analysis Tools (DIAT) by integrating sample clinical and genomics datasets using Informatics for Integrating Biology and the Bedside (i2b2) [2]. The i2b2 data warehouse and data management services were configured using Windows (XP) and Linux (Ubuntu 12.04). VMware Player and i2b2 Wizard [3] were used for environment setup, datasets were customized according to star schema, and data mapping and import was done using the Integrated Data Repository Toolkit [3]. Finally, cohort analysis and visualization was done using the i2b2 Web Client [2].

Conclusion

This work presented ICGED Infrastructure, roadmap and pilot prototype as a DIAT tool. In the future, we plan to extend DIAT using disease and genetic registries, develop RAPT using a machine learning model, CDSS using I2B2 plug-ins [2], and BDW using existing standards [4]. Some important challenges of personalized medicine, such as lack of experts/training, and social, ethical and legal aspects of genetic information use must be addressed in future research work.

Designing an Innovative Data Architecture for the Los Angeles Data Resource (LADR)

Sukrit Mukherjee[a], Robert A. Jenders[a,b], Sebastien Delta[a]

[a] *Center for Biomedical Informatics, Charles R. Drew University of Medicine and Science, Los Angeles, CA, USA*
[b] *Department of Medicine, University of California, Los Angeles, CA, USA*

Abstract

The Los Angeles Data Resource (LADR) is a joint project of major Los Angeles health care provider organizations. The LADR helps clinical investigators to explore the size of potential research study cohorts using operational clinical data across all participating institutions. The Charles R. Drew University of Medicine and Science (CDU) LADR team sought to develop an innovative data architecture that would aggregate de-identified clinical data from safety-net providers in the community into CDU LADR node. This in turn would be federated with the other nodes of LADR for a shared view in a way that was never available before. This led to a self-service system to assess patients matching study criteria at each medical center and to search patients by demographics, ICD-9 codes, lab results and medications.

Keywords:
Data Architecture, Electronic Health Record, Data Staging, Data Transformation, Grid Node Database, Federated Query.

Introduction

LADR is a joint project of major Los Angeles health care provider organizations. It facilitates clinical investigators to explore the size of potential research study cohorts across each participating institution using de-identified clinical data captured during customary clinical operations under the Clinical and Translational Science Institute (CTSI) program. CDU is a member of the CTSI but unlike the other LADR members that lacks clinical operations of its own, it has a rich history of partnerships with safety-net ambulatory providers serving the poor and minority neighborhoods of South Los Angeles. The CDU LADR team sought to develop a new data architecture that would aggregate data from disparate health information systems in the community into the CDU LADR node.

Methods

Using information provided by 'L.A. Net' - a primary care practice-based research network (PBRN) in the region partnering with more than 165 unique practice sites in Southern California - as a case study, we developed an extensible data architecture to obtain data from small health care organizations for LADR. L.A. Net had its own aggregator resource, the Reusable OMOP-SAFTINet Interface Transformation Adaptor (ROSITA) that supports the consumption, transformation and loading of clinical and administrative data from its partners' electronic health record systems (EHRs) and payer claims data into L.A. Net's grid node database. We designed an architecture to aggregate data from ROSITA and other individual EHRs into CDU LADR application server via a web service method of communication over the Internet.

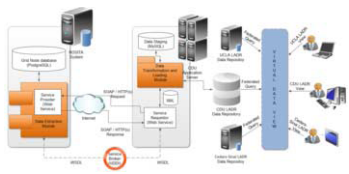

Figure 1 – The architecture for CDU LADR node

Results

The service requester module located on our server would request data, whereas the service provider module designed by us and placed on the ROSITA system would pull the requested operational clinical data from the grid node database, remove 18 specific identifiers (Safe Harbor Method) to de-identify the data thus complying with USA regulation regarding limited datasets and extract the de-identified data. Next, the service requester would receive data over SOAP or HTTPS protocol as XML to be loaded first into the staging database and later into the CDU's LADR Data warehouse. This XML file would be validated by the service requester for correct/expected values using an XSD file. A UDDI (Universal Description, Discovery and Integration) process would be defined to identify which software system should be contacted for which type of data. Thus, the CDU LADR node will have its own data repository and eventually be able to federate data with other participating institutions for a shared view.

Conclusion

We created a standards-based, flexible architecture to federate data with other LADR nodes for a shared view leading to a self service system. This system assessed patients matching study criteria at participating medical centers to search by demographics, ICD-9 codes, lab results, medications and to generate enrollment tables for clinical and translational research.

Curating and Integrating Data from Multiple Sources to Support Healthcare Analytics

Kenney Ng[a], Chris Kakkanatt[b], Michael Benigno[b], Clay Thompson[b], Margaret Jackson[b], Amos Cahan[a], Xinxin Zhu[a], Ping Zhang[a], Paul Huang[c]

[a] *IBM T.J. Watson Research Center, Yorktown Heights, NY, USA*
[b] *Pfizer Inc., New York, NY, USA*
[c] *Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA*

Abstract

As the volume and variety of healthcare related data continues to grow, the analysis and use of this data will increasingly depend on the ability to appropriately collect, curate and integrate disparate data from many different sources. We describe our approach to and highlight our experiences with the development of a robust data collection, curation and integration infrastructure that supports healthcare analytics. This system has been successfully applied to the processing of a variety of data types including clinical data from electronic health records and observational studies, genomic data, microbiomic data, self-reported data from surveys and self-tracked data from wearable devices from over 600 subjects. The curated data is currently being used to support healthcare analytic applications such as data visualization, patient stratification and predictive modeling.

Keywords:
Data Collection; Data Curation; Automatic Data Processing.

Introduction

The volume and variety of healthcare related data continues to grow, spurred on by the increasing adoption and use of electronic health records (EHRs), the explosion of omics data and the proliferation of actigraphy data from wearable self-tracking devices and mobile applications [1]. The use of this data for healthcare analytics such as data visualization, patient stratification, predictive modeling, personalized medicine and drug discovery will increasingly depend on the ability to appropriately collect, curate and integrate disparate data from many different sources [2]. The linking of many different types of data will allow the analysis and modeling of complex multi-dimensional interactions which can enable deeper insights.

Materials and Methods

Our data consist of the following diverse types and sources for over 600 subjects: (1) clinical data from EHRs and observational studies: demographics, family history, labs, vitals, diagnoses, medications; (2) genomic data: 500K single nucleotide polymorphisms (SNPs); (3) microbiomic data: abundances of gut microbial taxa; (4) self-reported data from surveys: behavioral, lifestyle, diet; and (5) self-tracked data from wearables: activity, sleep, diet.

To process these data, we developed a robust data collection, curation and integration infrastructure composed of the following stages: (1) **Data Collection**: gathering raw data from different sources. (2) **Data Understanding**: characterizing the data fields, types, and values. (3) **Data Validation**: checking the data against known quantitative relationships and expected values and for consistency across data types. Examples include checking lab values against standard ranges and using system physiology models to identify potential outliers in reported caloric intake data. (4) **Data Cleaning**: cleaning, normalizing and mapping data values and tagging the data with confidence indicators. Examples include using natural language processing to extract and normalize noisy medication values and map them to standard ontologies and flagging suspicious self-reported and self-tracked data based on compliance definitions. (5) **Data Integration**: merging data from different sources, resolving ambiguities, deduplication, normalizing units and dates and linking variables to the same subject. (6) **Data Enrichment**: creating new variables from the original data that are potentially more informative. Examples include the computation of genetic risk scores from the SNPs and the computation of scores from survey responses.

The data are then stored in a database using an n-tuple structure: subject identifier, feature identifier, feature value, confidence and event date that accomodates heterogenous data and supports the data retrieval needs of analytic applications.

Results

We found that a semi-automated approach, where most of the processing is automated but unhandled issues and errors can be flagged for human intervention, was important. Because some data were human reported and entered, they contained errors. As a result, it was important to have validation methods to check, clean, normalize and map the data when possible. In addition, we tagged the data instances with confidence indicators to allow analytic applications to select appropriate data subsets for their own use. When possible, we leveraged the different data types to perform cross type consistency checking. Incremental update capability was also needed to support the addition of new data to the database. Finally, we used an iterative development and refinement process in order to accommodate enhancements resulting from new data types, new instances of existing data types and feedback from the analytic applications that consume the curated data.

Conclusions

A robust infrastructure was successfully developed and used to collect, curate and integrate EHR, genomic, microbiomic, self-reported and self-tracked data to support healthcare analytics. Future work will enhance and extend the system to handle additional types of data including metabolomics, continuous biomarker data streams and medical imaging data.

Integrated Database And Knowledge Base For Genomic Prospective Cohort Study In Tohoku Medical Megabank Toward Personalized Prevention And Medicine

Soichi Ogishima[a], Takako Takai[a], Kazuro Shimokawa[a], Satoshi Nagaie[a], Hiroshi Tanaka[a], Jun Nakaya[a,b]

[a] *Dept. of Bioclinical Informatics, Tohoku Medical Megabank Organization, Tohoku University, Miyagi, Japan*
[b] *Dept. of Medical Informatics, Tohoku University School of Medicine, Miyagi, Japan*

Abstract

The Tohoku Medical Megabank project is a national project to revitalization of the disaster area in the Tohoku region by the Great East Japan Earthquake, and have conducted large-scale prospective genome-cohort study. Along with prospective genome-cohort study, we have developed integrated database and knowledge base which will be key database for realizing personalized prevention and medicine.

Keywords:

Tohoku Medical Megabank project, prospective genome-cohort study, integrated database and knowledge base

Introduction

To revitalize medical care and realize personalized prevention and medicine in the disaster area of Great East Japan Earthquake, the Tohoku Medical Megabank Organization has been established in February 2012. It aims at becoming a center for the reconstruction of the entire Tohoku region by conducting prospective genome-cohort study and developing the large-scale genome biobank toward personalized prevention and medicine.

In our prospective cohort study, we will recruit 150,000 people at Tohoku university, satellites, health clinics, and Iwate medical university, and collect (1) biospecimen (blood, urine) (2) questionnaire, (3) physical measurement as baseline and follow-up investigation. As for pathogenesis investigation follow-up, we will collect clinical data from electronic health records provided by Miyagi Medical and Welfare Information Network (MMWIN). MMWIN is expected to develop regional electronic network of medical records of most hospitals in Miyagi prefecture. Collected data will be de-identified and stored in a database of Tohoku Medical Megabank. Researchers in universities, institutes, and companies can apply withdrawal of biospecimen and data.

Materials and Methods

Integrated database provides large genome-cohort study data. It integrates various and vast amount of data. It is too huge to to grasp characteristic of data. Therefore, integrated database not only provides integration of data but also provides statistical significance and related knowledge in cooperation with knowledge base. Knowledge base provides existing knowledge of personalized prevention and medicine with NLP support for extraction of knowledge from literature, and novel knowledge by large-scale correlation analysis.

Results

Integrated database is a database for integration of genomic (omics), specimen, baseline & follow-up and clinical data. It is a relational database implemented by Oracle and MySQL RDMS. On the other hand, knowledge base is a database for integration of existing and novel knowledge by large-scale correlation analysis on integrated database. It is a RDF store implemented by Virtuoso. Our database is is too huge to grasp characteristic of data. Therefore, integrated database not only provides integration of data but also provides statistical significance and related knowledge in cooperation with knowledge base.

Statistical significance of selected data is provided in integrated database to characterize selected cohort; e.g., selected population has statistically significant bias in sex and alcohol intake. This characterization is expected to lead to hypothesis. Related knowledge of selected data is also provided in integrated database in cooperated with knowledge base; e.g., breast cancer is known to have a highly linked and causative SNPs. This provision of related knowledge is expected to accelerate studies.

Our project collected biospecimen and data provided by living people. Thus, data security and protection is very important. Our databases will be available with keeping security under our security policies (personal, very strong, strong and standard security policies).

Conclusion

The Tohoku Medical Megabank project is a national project conducting large-scale prospective genome-cohort study. We have developed integrated database and knowledge base which will be key database for realizing personalized prevention and medicine.

Abstract

The entire kidney transplantation process in Brazil is defined through laws, decrees, ordinances, and resolutions, but there is no defined theoretical map describing this process. From this representation it's possible to perform analysis, such as the identification of bottlenecks and information and communication technologies (ICTs) that support this process. The aim of this study was to analyze and represent the kidney transplantation workflow using business process modeling notation (BPMN) and then to identify the ICTs involved in the process. This study was conducted in eight steps, including document analysis and professional evaluation. The results include the BPMN model of the kidney transplantation process in Brazil and the identification of ICTs. We discovered that there are great delays in the process due to there being many different ICTs involved, which can cause information to be poorly integrated.

Keywords:

Kidney transplantation (MeSH E02.870.500); Systems integration (H01.770.787).

Introduction

The entire kidney transplantation process in Brazil is defined through laws, decrees, ordinances, and resolutions [1], but there is no defined theoretical map describing the kidney transplantation process. Business process modeling notation (BPMN) is the language most often used for representing processes diagrammatically [2]. It facilitates understanding among all the professionals involved in the process, and also helps organizations to measure their activities. The aim of this study was to identify the ICTs involved in the kidney transplantation process (KTP) in Brazil after the process has been analyzed and represented using BPMN.

Methods

This study was conducted in eight steps. Step 1: identification of the official digital documents relating to the KTP. Step 2: analysis of the the most important official documents (http://goo.gl/KbvHpp) using the methodology analysis on documents and processes. An initial representation of the KTP with ICTs identification was created using the Bizagi software (bizagi.com). Step 3: specialist evaluation using the Delphi methodology. Step 4: incorporation of a second official document (http://goo.gl/2a6HPi) and the assessment made by the specialist. Step 5: conduction of a survey to analyze and validate the second version of the KTP with four specialists. Step 6: research on the official website of each Brazilian state for additional legislation. Step 7: analysis of 11 documents using the methodology analysis on documents and processes. Step 8: conduction of an online survey to analyze and validate the results with the transplantation state units of all 26 Brazilian states and the federal district.

Results

The result of this work as a whole is much broader since it had to map the whole kidney transplantation process in Brazil (http://goo.gl/8VOH02). In total we analyzed 13 digital documents that resulted in two processes with 45 activities and events, six organizations involved, and six different stages. The ICTs identified included the federal IT system, phone (including mobile), fax, and email. We identified that from a total of 45 activities and events, seven are supported by a federal IT system, five by telephone, two by fax, and five by email. Thirty-three activities and events have no ICT supporting their implementation.

Conclusion

We note that there is still a great delay in the process, as there are diferent types and standards of ICTs involved, which can cause disparate data. This can result in rework, information loss, and delay in a process that could be conducted in a different and more efficient way. Adopting a single system for all entities involved in the process would be the best way to meet the process needs.

Abstract

The objective of this study is to determine the degree of similarities between the clinical terms used by physicians and nurses in their documentation.

Keywords:

NLP, NANDA, NOC, NIC, Health Informatics, Physician Documentation, Interprofessional Communication

Introduction

A coherent electronic record of patient care can aid shared understanding among health care team members and can improve patient and population outcomes. This point was illustrated when, lack of physician nurse documentation integration recently made international news when an Ebola patient was sent home in Dallas due to a lack of physician-nurse documentation sharing [1]. This lack of integration is commonplace in EHRs, including discharge documents. When patients are discharged, only the physician perspective is included in discharge summary. However, nurses provide the vast majority of direct care in the hospital. Nursing care can be documented in structured terminologies: NANDA (nursing diagnosis), NIC(nursing intervenitoins) and NOC (nursing outomes) for outcomes [2]. The similarities between the two profession's individual terms and terminologies is poorly understood and have been infrequently evaluated.

Methods

We utilized a previously de-identified published list [3] of 53,423 physician concepts, created from 8 years of physician discharge summaries. These concepts were assigned concept unique identifier (CUI) terms by MedLEE (a medical information extraction program) [3]. The complete list of 1,011 terms in NANDA-I, NIC, and NOC was generated by the HANDS [2] nursing plan of care software. Using the Unified Medical Language System (UMLS), each nursing term was mapped to a corresponding CUI [3]. The physician and nursing CUIs were assessed for being synonyms via UMLS.

Results

The 1,011 nursing terms map to 956 disctinct UMLS CUI concepts. Physicians only use 21% of these 956 nursing CUI concepts which represent a mere 0.4% of all CUI terms used by physicians in their documentation. Specifically, 28% of the NANDA-I terms, 13% of the NOC terms, and 24% of the NIC terms mapped to physician terms.

Discussion

The fact that only 21% of the nursing concepts are reflected in physician documentation demonstrates true differences in the professional practices. Prior work analyzing individual patients documentation demonstrated 17.4% of synonyms between MD/RN [4]. This study differs from others in that we specifically focus on examining the overlap of documentation terms used by physicians and nurses using comprehensive vocabularies that represent each profession reflecting the larger diversity of patient conditions.

Conclusion

The large discrepancy found between terms used by doctors versus nurses suggests the alarming potential for misunderstandings between the two professions. The finding also supports the assertion that nursing has a focus that is distinct from medicine, demonstrating a clear need for nurses to document care in the patient record so that the care is interoperable (can be analyzed to evaluate impact). The benefit of similarities calculations is the future potential for improving collaborative practice by ensuring concepts that are different are understandable to both professions. One limitation is that this study was conducted in a single hospital. Additionally, we evaluated hospital-wide usage and not term frequency. However,the findings indicate that both professions must be aware of differences in use of specific terms.

An HL7-FHIR-based Object Model for a Home-Centered Data Warehouse for Ambient Assisted Living Environments

Jonas Schwartze[a], Lars Jansen[b], Harald Schrom[b], Klaus-Hendrik Wolf[a], Reinhold Haux[a], Michael Marschollek[a]

[a] *Peter L. Reichertz Institute for Medical Informatics, University of Braunschweig and Hannover Medical School, Germany*

Abstract

Current AAL environments focus on assisting a single person with seperated technologies. There is no interoperability between sub-domains in home environments, like building energy management or housing industry services. BASIS (Building Automation by a Scalable and Intelligent System) aims to integrate all sensors and actuators into a single, efficient home bus. First step is to create a semtically enriched data warehouse object model. We choose FHIR and built an object model mainly based on the Observation, Device and Location resources with minor extensions needed by AAL-foreign sub domains. FHIR turned out to be very flexible and complete for other home related sub-domains. The object model is implemented in a separated software-partition storing all structural and procedural data of BASIS.

Keywords:

Ambient Assisted Living; HL7 FHIR; Data Warehousing.

Introduction

In an aing society, Ambient Assisted Living (AAL) has developed as a strategy to handle rising healthcare costs and sinking independence and self-reliance of elderly. Most existing AAL environments focus an assisting a single person with a composition of seperated home centered health-enabling techonolgies. [1] The BASIS project (Building Automation by a Scalable and Intelligent System) integrates sensors and actuators of all technical sub-domains in houses coplementary to AAL like building energy management, home safety, smart grid integration and housing industry. The architecture provides a central building manager with several meshed segment controller, each controlling a bus segment with any number of bus nodes (ref. [2]). Therefore, a data storage built upon a common domain model is needed. The main objective of this paper is to propose an HL7-FHIR-based resource model as foundation of a cross-domain data warehouse for home and building environments.

Methods

First, we defined a set of use cases representing each relevant sub-domain, in cooperation with the project partner. Socio-technical participants and domain related concepts were extracted to be reflected as possible object in the object model. Second, we listed existing domain-specific sensors and actuators with their measured data units or actions triggered.

Results

Since all use cases rely on saving, processing and reading (virtual) sensor data we used the resouce *Observation* as central starting point. Status and reliability are mandatory and derived from the underlying bus telegrams which deliver a validity bit to identify faulty measurements and possibly broken sensors. The element performer is fixed to a *Device* resource which in turn is used to represent a bus node. Actors in all use cases can be devided into persons (e.g. residents, sub-domain staff) or devices, which are sensors, actuators and complex devices. These devices are installed at certain locations (e.g. rooms, buildings) beeing part of certain other locations, modeled by the *Location* resource, which mainly relies on *position* and *part-of* to make locations nestable. To define more detailed technical data needed by most domains, we defined the extensions *technical*, *boundary* and *numbering*.

Conclusion

We presented an architecture and object model for a cross domain house bus system useable in AAL and other environments with a common object model as foundation of a home centered data warehouse. Whith the approach described we are able to store a broad range of sensor and actuator data as well as structural information of related sub-domains.

Data Curation: Improving Environmental Health Data Quality

Lin Yang[a], Jiao Li[a], Li Hou[a], Qing Qian[a]

[a] *Institute of Medical Information & Library, Chinese Academy of Medical Sciences, Beijing, China*

Abstract

With the growing recognition of the influence of climate change on human health, scientists' attention to analyzing the relationship between meteorological factors and adverse health effects. However, the paucity of high quality integrated data is one of the great challenges, especially when scientific studies rely on data-intensive computing. This paper aims to design an appropriate curation process to address this problem. We present a data curation workflow that: (i) follows the guidance of DCC Curation Lifecycle Model; (ii) combines manual curation with automatic curation; (iii) and solves environmental health data curation problem. The workflow was applied to a medical knowledge service system and showed that it was capable of improving work efficiency and data quality.

Keywords:

Environmental Health Research; Data Integration; Curation Workflow.

Introduction

The impact of climate change on public health, especially the increased severity of chronic air pollution exposure in areas, triggered numerous association studies. Since research has become heavily dependent on open access data, researchers need high quality data to support analysis. Data curation, which maintains quality, adds value, and provides reuse, could provide the necessary data quality. In this study, we construct a standard environmental health data curation workflow to achieve a high quality dataset for sharing.

Methods

In typical environmental health studies, researchers need to deal with data cleaning and processing case by case. We formulated this procedure in a standardrized workflow (see Figure 1) referring to Digital Curation Center (DCC) Curation Lifecycle Model. The workflow consists of six key compononts:

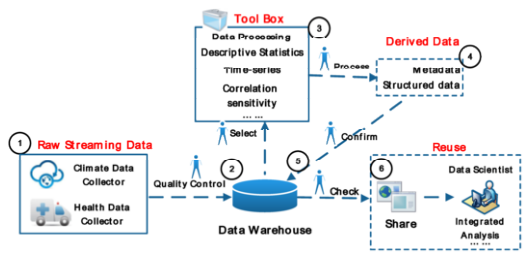

Figure 1 - The Environmental Health Data Curation Workflow

1. **Data Collection.** Raw, streaming data is collected from climate data and health data collectors.
2. **Data Ingest.** After quality assessment, curators upload qualifying data to a repository.
3. **Data Processing.** Computational tools help to clean the data and make basic analysis such as descriptive statistics, correlation analysis, time-series analysis, and sensitivity analysis. The processed data with statistical resutls is released.
4. **Data Structured Description.** Curators create metadata to describe the context of data.
5. **Data Storage.** Transform-derived data into long-term preservation formats and store for reuse.
6. **Data Reuse.** Share data via a online system for data scientists to access, integrated analyze, and promote knowledge transform.

Results

We applied the workflow to curate climate data and hosptial registry data. Climate data were collected from China ministry of environmental protection, including hourly air pollutants monitoring data and daily weather data. Registration data was from hospital emergency departments of a metropolis in China. Furthermore, the curated dataset was shared via a medical knowledge service system (http://med.ckcest.cn/) and the workflow provides backend support for the environmental health part of the system. The result shows that the workflow could help standardize environmental health data process, improve work efficiency and data quality.

[d] *Hospital Pablo Tobón Uribe, Colombia*
[e] *Texas A&M University, TX, USA*

Abstract

One of the ways to develop health simulations is through the use of computers. This paper presents the use of Intelligent Computer-Aided Instruction (ICAI) for the development of an interactive simulator for learning Cardio Pulmonary Resucitation (CPR) which incorporates online tutorials, training and evaluation.

Keywords:

Intelligent Computer-Aided Instruction (ICAI); Cardio Pulmonary Resucitation (CPR); Simulation; Guidelines Computer Assited-Instruction (GCAI).

Introduction

We developed a dynamic and adaptive case simulator that complements an online CPR course. WEST [1] and WUSOR [2] were early successes using health simulators. Early ICAI research demonstrated successful engineering of such systems to determine what knowledge a student was ready to acquire, and judge effective ways to intercede in the flow of problem solving. Our dynamic and adaptive case simulator is combined with a computer program based on protocol guidance to adapt to cases in a dynamic way.

Methods

Our system is an adapted version of the general ICAI architecture with the addition of an embedded GCAI for creating patient cases. The architecture for our system is:

1. Expert Knowledge Sources (KSs): generates problems and evaluates the student's solutions and steps. A representation of correct treatment protocol is parameterized, and is used to create a difference model of the student versus expert behavior.
2. Student-Model KSs: contains data about the student's interactions, selections, and other behaviors, along with a representation of understanding of the taught material. The appropriateness of each student action in the context of the case being solved and the recorded behavior differences is evaluated.
3. Tutor KSs: represents the data, information and knowledge to integrate the students understanding, the teaching method, and the subject area.

Figure 1– Achitecture of our coaching system for life support training

Results

Our tutoring KSs are successful in implementing the coaching pegadogy in CPR simulation based training. Our empirical approach to determined the data, information and knowledge required for the Tutoring Module resulted in an adapted version of the general ICAI architecture with the addition of an embedded GCAI for creating cases using a coaching pegagogy.

Discussion

The adapted version of the general ICAI architecture is now being used for other projects and is generalizable outside the CPR simulation context. One of these additional contexts is the design of a model of service delivery for both mother and fetus mediated by information and Communication Technologies(ICT) which enables monitoring of prenatal care, timely identification and management of high-risk obstetrics, and remote assistance for complicated situations.

On Analyzing Readmissions Using A Trajectory Model: Evidence From Israel

Ofir Ben-Assuli[a], Rema Padman[b], Martha Bowman[c], Moshe Leshno[d], Itamar Shabtai[e]

[a]Ono Academic College, Israel; [b]Carnegie Mellon University, Pittsburgh, USA; [c]Olmsted Medical Center, Minnesota, USA; [d]Tel-Aviv University, Israel; [e]College of Management Academic Studies, Rishon Lezion, Israel

Abstract

The problem of readmission, wherein patients are readmitted for the same or a related condition shortly after discharge, has become a challenge worldwide from care quality and financial perspectives. In this study, we explore 30-day readmission data for predicting who is likely to be readmitted and understanding key factors contributing to preventable readmissions using the developmental trajectory of creatinine level as a key laboratory marker of serious illness and a potential predictor of future readmission. Using Electronic Health Record data on 928 patients over ten different visits to emergency departments across Israel, we apply a semi-parametric, statistical, group-based trajectory model to elicit three distinct creatinine-based trajectories over time with differing 30-day readmission rates for males and females. Analysis of readmission risk stratification of the patient population using other relevant factors is ongoing research.

Keywords:

Readmission Prediction; Group-Based Trajectory Model; Creatinine Level; Electronic Health Record

Introduction

Readmission is the process of being admitted to a hospital, usually within 30-days of a patient's initial admission, costing healthcare systems billions of dollars every year [1]. Reducing hospital readmissions has long been a health policy goal because it can lower healthcare costs, improve quality, and increase patient satisfaction. In Israel, readmission rates have been relatively stable in the last decade, but at a fairly high level of 14% [2]. This study proposes a novel approach for predicting the risk of readmission and assessing the key factors leading to readmission that may facilitate improved patient stratification and follow up procedures.

Methods

Leveraging the availability of a rich and unique clinical dataset extracted from the EHR of the largest HMO in Israel, this preliminary study analyzes readmission risk prediction using semi-parametric, statistical, group-based trajectory models (GBTM) estimated using creatinine level as a specific clinical marker of serious illness [3, 4]. In particular, we examine how readmission risk may progress, based on creatinine levels, over 10 separate hospital admissions over time for an identified patient population of 928 patients presenting in the emergency department, what the different trajectories and their frequencies are, and the relationship of these trajectories to patient characteristics.

Results

Figure 1 shows the baseline model of progression of patients' health condition. There are three distinct trajectories describing the likelihood of readmission based on creatinine levels in the blood. Group 2, the first level, in stable state, includes almost 85% of the population. Group 1, with almost 13% of the population, has progressively worsening health conditions. Group 3 has only 2.5% of patients but is the most complex, with high average levels of creatinine in the blood, which seems to level off after 8 visits. By analyzing patient and visit characteristics to better understand factors that may be driving the readmission risk, we observe that the complex Group 3 also had the lowest readmission rate by gender. This non-intuitive result needs to be investigated further to better understand the drivers of risk in each patient subgroup.

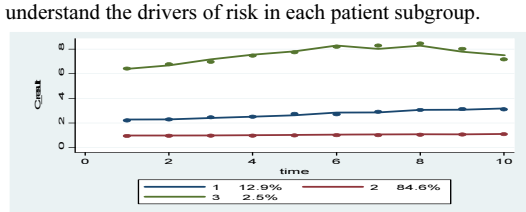

Figure 1. Baseline Model Results

Conclusion

Our early findings suggest that creatinine level based risk stratification can identify distinct groups of patients based on their presentation in the emergency department for admission and readmission purposes. Ongoing research will investigate additional time-invariant risk factors such as diagnoses and time-varying factors such as critical vitals and other laboratory values to improve risk stratification of this patient population.

Automated Detection of Health Websites' HONcode Conformity: Can N-gram Tokenization Replace Stemming?

Célia Boyer[a], Ljiljana Dolamic[a] , Natalia Grabar[b]

[a]Health on The Net Foundation, Geneva, Switzerland, [b] Université Lille 3, France

Abstract

Authors evaluated supervised automatic classification algorithms for determination of health related web-page compliance with individual HONcode criteria of conduct using varying length character n-gram vectors to represent healthcare web page documents. The training/testing collection comprised web page fragments extracted by HONcode experts during the manual certification process. The authors compared automated classification performance of n-gram tokenization to the automated classification performance of document words and Porter-stemmed document words using a Naive Bayes classifier and DF (document frequency) dimensionality reduction metrics. The study attempted to determine whether the automated, language-independent approach might safely replace word-based classification. Using 5-grams as document features, authors also compared the baseline DF reduction function to Chi-square and Z-score dimensionality reductions. Overall study results indicate that n-gram tokenization provided a potentially viable alternative to document word stemming.

Keywords:
Machine learning; N-gram; HONcode.

Introduction

The HON Foundation's Code of Conduct[1], comprised of eight procedural guidelines, helps to indicate the credibility of online health information for both website editors and users. Currently, HON expert reviewers manually assess, re-assess, and certify health websites for compliance with the HONcode principles of conduct. The authors report herein a feasibility study to determine whether a specific machine learning algorithm based on n-gram representation of a document's content, can assist in the HONcode certification process.

Methods

In the scope of KHRESMOI[2] project we have developed a system for automated detection of HONcode principles [1]. Based on previous experience [1], the Naive Bayes machine learning algorithm is chosen in this study to compare the results obtained when various size n-grams (e.g. C3, C4, C5) and stems (W1p) are used as document tokens to the results of the word tokens (W1) baseline. The goal was to determine the extent to which words might be replaced as tokens while not sacrificing system classification performance. Keeping 30% of top ranked features, we also explored DF, Chi-square and Z-score dimensionality reduction for the 5-gram tokenization.

Results

Authors chose precision (P), recall (R) and F_1-measure to represent the quality of the classification. The results indicate that the tokenization method that produces the best precision results varies for each HONcode criterion. While W1 tokenization provides highest precision and highest F_1 value for "Authority" (0.64; 0.69) or "Privacy" (0.91; 0.94), highest precision for the "Reference" is obtained for 5-gram tokenization. For the "Justifiability" criterion the most balanced precision/recall tradeoff is achieved by C3.

The relative difference in precision between W1p and C5 spanning from -7.25% to 3.45% as well as similar behavior to W1 or W1p in relation with dimensionality reduction (e.g. features kept: 80% vs. 30%. Precision loss W1: -11.08%; W1p: -10.28%; C5: -10.41%) indicate the usability of C5 as an alternative to stem or word for the English language.

Results also show that both DF and Z-score dimensionality reduction significantly outperformed the Chi-square in terms of precision, with the exception of the "Contact details" criterion for the C5 tokenization.

Conclusion

Our study results indicate that the n-gram approach is a viable alternative to both word and stem tokenization. Choosing the "correct" dimensionality reduction algorithm can additionally improve the classification results. Accounting for importance of linguistic treatment for morphologically complex languages, and the baseline established here, one can suppose that the language-independent n-gram approach would not only be interchangeable but also might result in better performance for languages other than English.

Data Science Solution to Event Prediction in Outsourced Clinical Trial Models

Daniel Dalevi[a], Susan Lovick[b], Helen Mann[b], Paul D. Metcalfe[a], Stuart Spencer[b], Sally Hollis[b], David Ruau[a]

[a]*Advanced Analytics Centre, Biometrics and Information Sciences, AstraZeneca, Sweden/UK*
[b]*Biometrics and Information Sciences, AstraZeneca, UK*

Abstract

Late phase clinical trials are regularly outsourced to a Contract Research Organisation (CRO) while the risk and accountability remain within the sponsor company. Many statistical tasks are delivered by the CRO and later revalidated by the sponsor. Here, we report a technological approach to standardised event prediction. We have built a dynamic web application around an R-package with the aim of delivering reliable event predictions, simplifying communication and increasing trust between the CRO and the in-house statisticians via transparency. Short learning curve, interactivity, reproducibility and data diagnostics are key here. The current implementation is motivated by time-to-event prediction in oncology. We demonstrate a clear benefit of standardisation for both parties. The tool can be used for exploration, communication, sensitivity analysis and generating standard reports. At this point we wish to present this tool and share some of the insights we have gained during the development.

Keywords:
Event prediction; oncology; visualizations; R; Shiny

Introduction

Time to event analysis is generally used when assessing the efficacy of newly developed oncology drugs. In these studies, the timing of analysis is often based on reaching a target level of events. Therefore it is desirable to predict the times of these landmark events for logistic planning – before and during the course of the trial [1]. Typical design related information are: length of trial, recruitment period, shape of recruitment, randomization balance, expected rates and statistical test parameters (alpha, power etc). In the case of an ongoing trial we also have accumulated data. We have implemented a web application using RStudio Shiny server together with an R-package simplifying the analysis, the learning curve and hand-over time while increasing interactivity, reproducibility, quality and trust.

Materials and Methods

This section describes some of the theory behind the event predictions analysis. Non-linear recruitment is used together with a survival function for describing the time-to-events. Constant or monotonically increasing or decreasing risks are modelled using exponential or Weibull distributions. There are two prediction modes. In the "from parameters" mode, where there is little or no data, study design parameters are used to specify an exponential model as the basis to predict the required number of events, the critical hazard ratio, predicted time points, the power and relative risks. In the "from data" mode, a Weibull model is fitted to the accumulated data.

Predictions for patients without an event is generated by simulating new event times. All methods are implemented in R and Shiny server is used to produce the web-interface.

Results

A simple use-case: a CRO statistician investigates an ongoing clinical trial with 979 patients currently recruited and 699 events observed. Using the online web interface the model predicts that the 900 events target will be reached in September 2016 with a confidence interval of [Aug 2016, Oct 2016]. The CRO sends the report to the study team who can easily reproduce and validate the results. The interactivity allows easy exploration of the prediction and gives an immediate feel for the sensitivity towards changes in settings.

Conclusion

Enabling CRO and Pharmaceutical companies to work on harmonised statistical computing platforms developed in-house has the potential to reduce data transfer cost and communication time. Event prediction in oncology trials can be complex and this approach enables easy diagnostics and sensitivity analysis with a low learning curve. The tool can be used for exploration, communication, sensitivity analysis and for generating standard reports, as well as facilitating single-point implementation of updates, bug fixes and expansions.

Acknowledgments

We would like to thank Andrew Stone for his support.

Improving Hospital-wide Patient Scheduling Decisions by Clinical Pathway Mining

Daniel Gartner[a], Ines V. Arnolds[b] and Stefan Nickel[b]

[a] *The H. John Heinz III College, Carnegie Mellon University, Pittsburgh, PA, USA*
[b] *Institute for Operations Research, Discrete Optimization, Karlsruhe Institute of Technology, Karlsruhe, Germany*

Abstract

Recent research has highlighted the need for solving hospital-wide patient scheduling problems. Inpatient scheduling, patient activities have to be scheduled on scarce hospital resources such that temporal relations between activities (e.g. for recovery times) are ensured. Common objectives are, among others, the minimization of the length of stay (LOS). In this paper, we consider a hospital-wide patient scheduling problem with LOS minimization based on uncertain clinical pathways. We approach the problem in three stages: First, we learn most likely clinical pathways using a sequential pattern mining approach. Second, we provide a mathematical model for patient scheduling and finally, we combine the two approaches. In an experimental study carried out using real-world data, we show that our approach outperforms baseline approaches on two metrics.

Keywords:
Artificial Intelligence; Linear Programming

Introduction

Hospital resources become more and more scarce which challenges hospital-wide coordination of patient care. To plan treatments throughout the patients' LOS, high-quality information about planned activities and time lags between them, henceforth denoted as clinical pathways (CP), is necessary. When information about patients is incomplete, effective and efficient planning of care processes is difficult.

CPs support consistent application of evidence-based medicine for the best patient outcomes. Often this has the effect of placing an emphasis on reduction of unwarranted variation in clinical practice [4]. A brief overview of similarity measures of and adherence to CPs are presented in [1]. In this poster, we present and evaluate a new and unusual way of predicting CPs. Similar to Gartner and Arnolds [1], we first learn significant CPs from large transactional data and incorporate them into a mathematical model. The novelty is, however, that we perform patient scheduling in addition to layout decisions.

Methods

Learning significant CPs from data can be seen as a sequential pattern mining task. One out of many algorithms that tackle the problem is described in [1] It also provides an overview of related work. A probabilistic prefix-tree acceptor (PDFA) is learned from data. States are merged recursively by using a similarity measure, and the diagram probability can be inferred and interpreted as the transition probability between specialties. We incorporate most likely transitions into an extension of a patient flow problem with fixed admission dates presented in [2] which can verbally be described as follows: Binary decision variables decide whether or not an activity is scheduled for a period. The objective function minimizes LOS. Precedence constraints capture clinical pathways, resource constraints for overnight resources capture scarce beds. Further constraints ensure that each activity is assigned to exactly one period of its time window.

Results

We extracted the specialty flow from data of 16,000 patients obtained from a German academic teaching hospital. Our computational study reveals that using IBM ILOG CPLEX concert technology, the computation time for each cross-validation run takes less than 1 minute on a 2.4 GHz PC. Our mean absolute error and LOS deviation reductions range between 2% and 5%, depending on the PDFA generalization.

Conclusion

In this poster, we introduce the connection between a sequential pattern mining approach and a patient scheduling problem. We show that our approach outperforms baseline approaches on two evaluation measures. Future work may incorporate our approach into the platform presented in [3].

Abstract

The objective of the SYNODOS collaborative project was to develop a generic IT solution, combining a medical terminology server, a semantic analyser and a knowledge base. The goal of the project was to generate meaningful epidemiological data for various medical domains from the textual content of French medical records. In the context of this project, we built a care pathway oriented conceptual model and corresponding annotation method to develop and evaluate an expert system's knowledge base. The annotation method is based on a semi-automatic process, using a software application (MedIndex). This application exchanges with a cross-lingual multi-termino-ontology portal. The annotator selects the most appropriate medical code proposed for the medical concept in question by the multi-termino-ontology portal and temporally labels the medical concept according to the course of the medical event. This choice of conceptual model and annotation method aims to create a generic database of facts for the secondary use of electronic health records data.

Keywords:

Natural language processing; Knowledge base; Medical records; Information Storage and Retrieval Methods; Semantics; Terminology;

Introduction

Most information extraction technology requires a corpus of annotated medical records for development and evaluation. Our annotation approach was clinically-oriented in order to develop and evaluate medical expert rules involved at different levels of the solution. The objective of this paper is to describe how we developed a conceptual model based on the manual annotation of medical documents, which will be used as "gold standard" for the development and evaluation of the knowledge base.

Methods

The first source of the data was the research project ALADIN-DTH, in which 1600 medical textual documents were extracted and de-identified from four French university hospitals. The second source of data consists of 300 medical documents of patients diagnosed with colon cancer at a French referral center for oncology care. A health extractor (ECMT V2) was used to obtain the health concepts included in the medical reports. This extractor was developed by the CISMeF team, using their cross-lingual multi-termino-ontology portal (55 terminologies).

Results

MedIndex was an application developed by UMR UCBL CNRS 5558 for the annotation of medical concepts by semi-automatic methods (Figure 1).

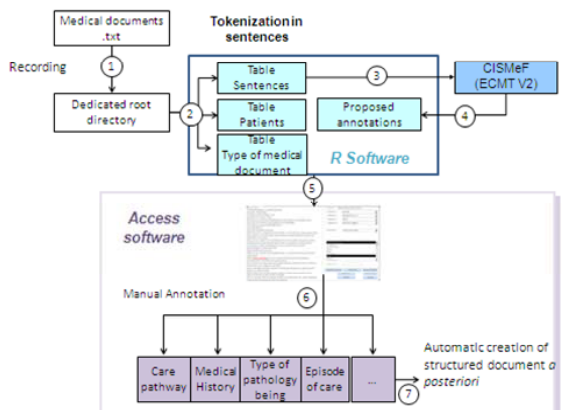

Figure 1– MedIndex dataflow

The database obtained by MedIndex is the conceptual model of the knowledge base that will be developed further for the SYNODOS solution.

Conclusion

The originality of our annotation method lies in the fact that it was not only oriented towards identifying key clinical entities mentioned in the text or determining the relationships between entities [2]. Additionally, it is oriented towards identifying medical interpretation in the context of a care pathway.

[e]*Department of Internal Medicine, Gohyakuyama Clinic*

Abstract

Atmospheric pollution affects the health through complex mechanisms and to varying degrees. However, even by secondary usage of retrospective HIS and "AEROS" data, screening can be performed for specific ICD10 diseases caused by environmental factors. Our screening method showed good agreement with doctors' common knowledge on the relationship between atmospheric data and disease. Examples include the higher incidence of influenza at low temperatures and dry skin caused by low humidity, etc. We need to examine the method further in order to make it simpler, easier and more robust.

Keywords:
Secondary usage; HIS; "AEROS"; ICD10; "Quartile"; Screening method.

Introduction

We used two data sources for our research: AEROS (Atmospheric Environmental Regional Observation System), which is a database of government-administered real-time (by hour bat used for the daily average) regional atomospheric pollution data, including the temperature and humidity, and the in- and out-patient disease records out of HIS.

Methods

The environmental factors included in "AEROS" that were adopted for this research were the levels of 20 air pollutants (SO2, CO2, PM2.5, etc.), and the humidity and temperature for the period of 2010-2012.

The disease records comprised 520,000 cases for that period. We applied the "Quartile" screening method as follows;

1. Three quartiles are defined for each environmental item for each year, so that four quartile intervals were obtained.
2. For each quartile interval, the corresponding averages, N1 to N4, were computed for each disease in ICD10 coding.
3. Ratios Q^+=N4/N1, Q^-=N1/N4 are indicators of the intensity of the positive or negative environmental impact on each disease.
4. Data with Q^+ or Q^- greater than 1.5 during the three years were extracted.
5. 7-day moving averages were also computed to adjust for the weekday effects. Lag effects of environmental factors were adjusted for by shifting by 0 to 3 days.
6. Finally, the three-year geometric means were listed as good evidence for the correlations between environmental factors and disease. The criteria obtained thus provide us with an integrated perspective on the environment and health and the relationship between the two.

Results

Our "Quartile" screening method was considered to have high validity because of the large volume of the data (520,000 cases) and the high level of consistency of the data through the three-year period. Furthermore, our screening method showed good agreement with doctors' common knowledge on the relationship between atmospheric data and disease. For example, our results showed a relationship between

1. Influenza and low humidity (J Shamana & M Kohmn,2009),
2. Dry skin and low humidity (M Egawa,et al. 2002),
3. Ophthalmological inflammatory disease and atmospheric factors (NO2,NOX),
4. Chronic disease (cancer) and atmospheric factors (NOX) in terms of the patients' hospital visits.

Conclusion

Our "Quartile" screening method has the following four advantages in the analysis of large data: 1) simplicity, 2) readiness, 3) cost & time efficiency, and 4) robustness.

Impact of data quality assessment on development of clinical predictive models

Jitendra Jonnagaddala [a,b,c], Siaw-Teng Liaw [a] and Pradeep Ray [d]

[a] *School of Public Health and Community Medicine, UNSW Australia*
[b] *Asia-Pacific Ubiquitous Healthcare Research Centre, UNSW Australia*
[c] *Prince of Wales Clinical School, UNSW Australia.*
[d] *Asia-Pacific Ubiquitous Healthcare Research Centre, UNSW Australia.*

Abstract

Data quality plays a very important role in predicting clinical outcomes. Data quality is multi dimensional and most relevant studies consider just one or two dimensions. In this study a systematic data quality assessment is performed using four data dimensions. The results demonstrate that performance of predictive models improves when the quality of the data is assessed and addressed systematically.

Keywords

predictive modeling; data quality assessment; data preprocessing

Introduction

Low data quality can be a serious issue in predictive modeling. The typical workflow of predictive model development includes data preprocessing, feature selection, model development and evaluation steps. There are various studies about data preprocessing and the effects of techniques employed on overall prediction problem [1, 2, 3]. However, these studies did not preprocess data from a systematic data quality assessment (DQA) perspective. Thus, the objectives of this study are i) to systematically assess data quality using four different data quality dimensions ii) develop predictive models using four algorithms to predict in-hospital mortality. The algorithms used are Naïve bayes (NB), Random forest (RF), Support Vector machines (SVM) and Multi-layer perceptron (MLP) and iii) present the effects of the systematic DQA on the performance of predictive models.

Methods

The authors used the dataset which was provided as part of the 2012 Physionet Computing in Cardiology (CinC2012) challenge [4]. Four different predictive models were developed to predict whether an ICU patient survives hospitalization. The selected data quality dimensions include completeness, consistency, correctness and contextual accuracy. Data quality metrics were calculated in percentages on each column of the dataset using the selected data quality dimensions. The calculated metrics were used to systematically profile the dataset to select relevant techniques (imputation or deletion or classification) to address the data quality issues [5]. All available variables in the dataset were used as features. The performance of the developed predictive models were measured using accuracy (represented in percentage), positive prediction value (PPV) and the F-score.

Results

DQA was performed on both training and test sets using completeness, consistency, correctness and contextual accuracy dimensions. DQA Results show that a significant amount of variables had more than 50% of missing data. The final results suggest that performing DQA systematically improves the performance of predictive models. The results are consistent with results reported in studies where just one or two data quality dimensions are used [3]. The RF based predictive model was the one which was most affected by the DQA and it showed marked improvement when all the data quality issues identified using data quality dimensions were rectified.

Conclusion

In this study, the authors explored the impacts of data quality on clinical predictive modelling by performing a systematic DQA. The authors observed that NB based model performance remained consistent but in the end the RF based model outperformed the rest of the models after DQA. The results also demonstrate that performance of predictive models improve when the quality of the data is assessed and addressed systematically.

Evaluating Methods for Identifying Cancer in Free-Text Pathology Reports Using Various Machine Learning and Data Preprocessing Approaches

Suranga Nath Kasthurirathne, BEng[a], Brian E. Dixon, MPA, PhD[b,c], Shaun J. Grannis, MD, MS[b,d]

[a]*Indiana University School of Informatics and Computing, Indianapolis, IN, USA*
[b]*Regenstrief Institute, Indianapolis, IN, USA*
[c]*Indiana University Fairbanks School of Public Health, Indianapolis, IN, USA*
[d]*Indiana University School of Medicine, Indianapolis, IN, USA*

Abstract

Automated detection methods can address delays and incompleteness in cancer case reporting. Existing automated efforts are largely dependent on complex dictionaries and coded data. Using a gold standard of manually reviewed pathology reports, we evaluated the performance of alternative input formats and decision models on a convenience sample of free-text pathology reports. Results showed that the input format significantly impacted performance, and specific algorithms yielded better results for presicion, recall and accuracy. We conclude that our approach is sufficiently accurate for practical purposes and represents a generalized process.

Keywords:

Public health reporting; decision models; ontologies; cancer; pathology; data preprocessing.

Introduction

Cancer case reporting is often delayed and incomplete [1]. Automated methods for identifying public health reportable cases can address this issue [2], yet a substantial amount of cancer case-related data are captured as free-text making it challenging to interpret [3]. We sought to assess approaches to identify cancer cases from free-text pathology reports to (a) determine whether we could achieve acceptable accuracy using a generalizable approach that does not require complex dictionaries, grammars or ontologies; (b) compare various candidate decision models; and (c) evaluate how data input format affects decision model accuracy.

Methods

We identified seven keywords associated with the presence of cancer in pathology reports. Each free text report was parsed and separate counts tabulated for the presence of each keyword either in positive or negated contexts using the Negex algorithm. We evaluated two preprocessed data input vectors. The first input vector ("raw count") contained positive counts (C_p) and negated counts (C_n) for keywords in each report. The second ("four-state") reduced these to a single value per keyword: 1=($C_p > C_n$); 2=($C_n > C_p$); 3=($C_p = C_n$) and 4=keyword absent. We evaluated logistic regression, naïve bayes (NB), k-nearest neighbor, random forest (RF), and J48 decision tree decision models implemented in Weka software version 3.6.10. The precision, recall, and accuracy was calculated for each input format combination.

Results

Each decision model and input format combination yielded satisfactory results. However, the "raw count" input format outperformed the "four-state" input for all three performance measures. The NB decision model produced statistically significant lower results for accuracy ($p < 0.01$); the remaining methods showed no difference as a group. For recall, all decision models showed no difference as a group. For precision, both RF and NB showed lower values ($p < 0.01$); the remaining methods were indistinguishable.

Discussion

Overall results indicated that the "raw count" input format outperformed the "four-state" format. Although we achieved reasonable performance while avoiding the use of complex dictionaries or ontologies, this approach occasionally failed to identify cases when text reports contained only disease specific terms and the seven generic keywords were absent. We conclude that our approach represents a generalized process that can be adapted for many additional clinical use cases, and is accurate enough for practical purposes.

A Metadata based Knowledge Discovery Methodology for Seeding Translational Research

Cartik R Kothari[a], Philip RO Payne[a,b]

[a]*Department of Biomedical Informatics, School of Medicine, The Ohio State University, Columbus, OH, USA*
[b]*Data Analytics Collaborative, The Ohio State University, Columbus, OH, USA*

Abstract

In this paper, we present a semantic, metadata based knowledge discovery methodology for identifying teams of researchers from diverse backgrounds who can collaborate on interdisciplinary research projects: projects in areas that have been identified as high-impact areas at The Ohio State University. This methodology involves the semantic annotation of keywords and the postulation of semantic metrics to improve the efficiency of the path exploration algorithm as well as to rank the results. Results indicate that our methodology can discover groups of experts from diverse areas who can collaborate on translational research projects

Keywords:
Knowledge Discovery; Translational Research; Semantics.

Introduction

Translational science research [1] involves the collaboration of scientists from various disciplines and the identification of viable interdisciplinary groups of scientists is crucial to the success of translational research initiatives. We describe a methodology to identify interdisciplinary teams of researchers to collaborate on translational research projects as part of the Discovery Themes initiative at The Ohio State University.

Materials and Methods

Raw data for identifying cross-disciplinary research teams was gathered by compiling large lists of research documents from the last 5 years, which included: (a) funded research grant proposals and (b) abstracts of every article in every journal indexed by SCOPUS, restricting to only the top 10% of the most productive researchers in each discipline determined by Academic Analytics. From this corpus, text mining techniques compiled a set of approximately 60K keywords. Then, each keyword was categorized under one of 17 research disciplines or subheadings following the classication scheme used by the United States Library of Congress. We defined semantic metrics for each keyword taking into account its: a) specificity and b) usage frequency. Given the subheading under which a keyword was classified, specificity is the length of the path from the keyword to the root of the subject heading hierarchy. The usage count of the keyword was part of the input to the algorithm. Given the widely varying usage counts, we used a logarithm of the frequency. The semantic metric of the keyword is defined as the ratio of the specificity to frequency; it varies directly with specificity but inversely with usage frequency. The semantic distance between two keywords is the sum of the depths of the keywords and the semantic distance between the subject headings they belong to, except if the keywords belong to the same hierarchy when the semantic distance between them is zero. The path finding algorithm was then used to link researchers connected by 5 keywords in the graph using the semantic metrics to prune the search space.

Results and Conclusions

Starting with ~1400 researchers who were affiliated with The Ohio State University, paths with 5 keywords were generated to link them with ~14000 outside researchers (Figure 1).

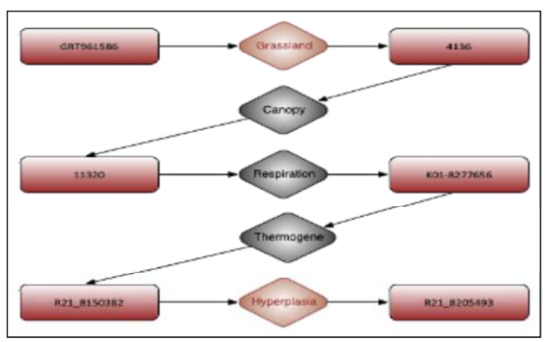

Figure 1: An example of a generated path

Our path finding algorithm is different from classical clustering techniques in that it groups data points (researchers) on the basis of their differences instead of on the basis of their similarities. A limitation of our work is the reliance on simple keywords to connect the researchers. The classification of keywords to specific subheadings and the addition of semantic metrics addresses this limitation. However, the classifications themselves are subjective; derived from manual annotation. The identity of the associated researchers could be very useful in identifying the correct context of context-sensitive keywords, given all the researchers have been de-identified in the input data set.

Acknowledgments

This research was supported by the National Cancer Institute of the National Institutes of Health under Award Number P01CA081534. We would like to acknowledge preliminary analysis work by Jason Sullivan and Julia Carpenter-Hubin.

Restricted Versus Unrestricted Search Space: Experience from Mining a Large Japanese Database

Hendrik Nienhoff[a], Ursula Huebner[a], Andreas Frey[b], Mareike Przysucha[a], Michio Kimura[c]

[a] *Health Informatics Research Group, Osnabrueck University of Applied Sciences, Germany*
[b] *Nuertingen-Geislingen University, Germany*
[c] *Hamamatsu University School of Medicine, Japan*

Abstract

The aim of this study was to investigate whether standard Big Data mining methods lead to clinically useful results. An association analysis was performed using the apriori algorithm to discover associations among co-morbidities of diabetes patients. Selected data were further analyzed by using k-means clustering with age, long-term blood sugar and cholesterol values. The association analysis led to a multitude of trivial rules. Cluster analysis detected clusters of well and badly managed diabetes patients both belonging to different age groups. The study suggests the usage of cluster analysis on a restricted space to come to meaningful results.

Keywords:

diabetes mellitus; data mining; association analysis; cluster analysis.

Introduction

Data mining methods have become the core of discovering knowledge in large datasets (Big Data) [1] and have been applied in medicine [2] [3]. The aim of this study was to evaluate the usefulness of different standard data mining methods for finding useful patterns in a dataset of diabetes patients.

Methods

Based on a clinical data warehouse at the Hamamatsu University hospital, 26,890 patients were analyzed to extract patients diagnosed with diabetes type 2 (ICD10-Code 'E11'). After extensive data transformation and cleansing, association and cluster analyses were performed (using the WEKA Tool) to detect assocations of co-morbidities within the group of diabetes patients and to investigate if diabetes patients could be clustered by age, blood sugar and cholesterol values into different sub-groups. Both analyses belong to the unsupervised and describing methods of data mining [1]. Whereas the association analysis was performed on a search space of 73 variables, the cluster analysis was restricted to three variables.

Results

Using similar minimum support and confidence values as [2], 45,314 association rules were identified out of which the five strongest are shown in Table 1, ranked by confidence. Clustering with k=4 clusters showed that high levels of blood sugar went along with high cholesterol levels, each for younger and for elderly patients (Tab. 2).

Table 1– Five strongest association rules identified (n=1,339)

Rule (X→Y)	n	Supp.(X)	Conf. X→Y
H26 → H52	311	0.23	0.95
I20 → I10	320	0.24	0.84
I50 → I10	458	0.34	0.74
I50 → E78	458	0.34	0.68
E78 → I10	735	0.55	0.66

E78: Hypercholesterolaemia; H26: Other cataract; H52: Disorders of refraction; I10: Essential (primary) hypertension; I20: Angina pectoris; I50: Heart failure

Table 2– 4-Cluster centres for low-density lipoprotein

		Age		HbA_{1c}		LDL	
Clstr	n	mean	σ	mean	σ	mean	σ
1	135	68.7	7.5	8.6	1.2	85.4	25.8
2	273	75.1	5.2	6.6	0.7	60.4	17.4
3	191	56.2	8.1	6.3	0.7	66.6	19.0
4	63	39.9	9.3	8.6	1.8	89.2	26.5
total	**662**	**65.0**	**13.3**	**7.1**	**1.4**	**70.1**	**23.6**

Discussion

The association rules identified are similar to the results of Kim et.al. [2], who also detected primarily trivial rules. The cluster analysis showed that patients could be separated into two groups of diabetes patients with well or badly managed longterm blood sugar values. Well managed patients also had lower LDL values. These findings were independent of age. In summary, restricting the search space by knowledge yielded more useful clinical patterns. Data analysis was only possible after elaborate and time-consuming preprocessing.

Interpreting Medical Information Using Machine Learning and Individual Conditional Expectation

Yasunobu Nohara[a], Yoshifumi Wakata[a], and Naoki Nakashima[a]

[a] *Kyushu University Hospital, Fukuoka, Japan*

Abstract

Recently, machine-learning techniques have spread many fields. However, machine-learning is still not popular in medical research field due to difficulty of interpreting. In this paper, we introduce a method of interpreting medical information using machine learning technique. The method gave new explanation of partial dependence plot and individual conditional expectation plot from medical research field.

Keywords:

Machine learning; Partial dependence plot; Individual conditional expectation.

Introduction

Recently, machine-learning technique, such as deep learning and random forest, has been spreading many fields. However, machine-learning is still not popular in medical research field. One of the reasons is difficulty of interpretation. In machine learning, prediction accuracy is a main target of the research and easy for interpretation is not sufficiently considered. In this paper, we introduce a method of interpreting medical information using machine learning technique.

Methods

Given explanatory variables $x_1, ..., x_p$, and patients' outcome y. Let N be the number of subjects. We assume predictor f is given as a black box but calculates the outcome y with high accuracy using explanatory variables $x_1, ..., x_p$ using machine learning technique. How do we study the effect of an explanatory variable x_i on patients' outcome? A naive method is comparing each explanatory variable x_i and outcome y. However, other explanatory variables also affect the outcome; therefore, we don't get accurate effect of x_i. The best way to study the effect of x_i is using the same conditions expected for the explanatory variable and investigating the difference among the outcome. It is almost impossible to recruit patients who have same age, sex, blood pressure and other conditions in a real experiment. On the other hand, we can easily calculate outcomes under various conditions on the predictor, and we use this predicted value instead of experiment result.

If we study the effect of a variable x_i, it is natural to use mean outcome under the various conditions. Let x_i^j be an explanatory variables x_i of subject-j and mean outcome fixing x_i to X is given as:

$$F_i(X) = \frac{1}{N}\sum_{j=1}^{N} f(x_1^j, x_2^j, ..., x_{i-1}^j, X, x_{i+1}^j, ..., x_p^j) \quad (1)$$

Figure 1 shows an example. If we want to compare the effect of operation-A and operation-B, we directly compare ***F(A)*** and ***F(B),*** because this comparison is simulation but under the same condition excepted for operation method.

In fact, Equation (1) is the same as the definition of partial dependence plot (PDP), which is a visualization method of high-dimensional function proposed by Friedman [1]. Individual conditional expectation (ICE) plot is an extension of PDP proposed by Goldstein [2]. ICE plot can express interaction of explanatory variables. Centered ICE (c-ICE) [2] is given as following equation (2)

$$F_i^{center}(X, x^*) = F_i(X) - F_i(x^*) \quad (2)$$

If we suppose that f is additivity, that is

$$f(x_i, \{x_j\}_{j\neq i}) = g(x_i) + h(\{x_j\}_{j\neq i}) \quad (3)$$

In this case, c-ICE is given as follows

$$F_i^{center}(X, x^*) = \frac{1}{N}\sum_{j=1}^{N}\{g(X) - g(x^*)\} \quad (4)$$

Equation (4) means that c-ICE expresses the effect of expalantory variable x_i only and does not depend on other explanatory variables if f is additivity.

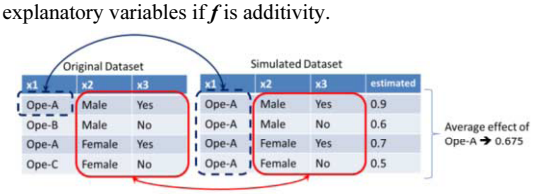

Figure 1 – Original dataset and simulated dateset of partial dependence plot

Conclusion

In this paper, we proposed a new explanation of partial dependence plot and individual conditional expectation plot from medical research field.

Abstract

This paper presents the profile and experience of sexuality generated from a data mining classification task. We used a database about sexuality and gender violence performed on a university population in southern Brazil. The data mining task identified two relationships between the variables, which enabled the distinction of subgroups that better detail the profile and experience of sexuality. The identification of the relationships between the variables define behavioral models and factors of risk that will help define the algorithms being implemented in the data mining classification task.

Keywords:

Medical Informatics; Artificial Intelligence; Data Mining; Sexuality.

Introduction

Data mining consists of applying algorithms to identify and analyze information in order to produce patterns or models of the data [1]. The main topic of this study is sexuality, which is considered inherent to life and health, and is expressed early in humans as one of the indices that measure the level of quality of life [2]. This paper presents the profile and experience of sexuality in a university population in southern Brazil generated from a data mining classification task.

Methods

The database used for this study addressed the sexuality profile and vulnerability to sexually transmitted diseases (STDs) and acquired immune deficiency syndrome (AIDS) in a university population in southern Brazil. First, the data was pre-processed, and then the application for fuzzy clustering under development at UNESC [**3**] was used. The classification of data was carried out using the J48 algorithm in the Waikato Environment for Knowledge Analysis software (WEKA). In addition to the complete base (classification 1), an analysis of the database was examined using only males (classification 2), as well as examining a data set containing both genders but eliminating the variables of the all-male responses (classification 3). Only the rules belonging in trees with at least 70% of the records correctly classified and associations in 5% of the sample were used. We used accuracy for the evaluation of the knowledge generated.

Results

We conducted 204 experiments that resulted in 8728 rules. Classification 1 returned 3727 rules(0.76 accuracy [IC 95%=(0.73;0.80)]); classification 2 returned 1699 rules(0.75 accuracy [IC 95%=(0.71;0.79)]); and classification 3 returned 3302 rules (0.76 accuracy [IC 95%=(0.72;0.80)]). The profile obtained from the analysis was similar to that found in the literature. By observing the age of sexual activity onset, the J48 algorithm not only isolated information (15-19 years of age), but also found that this group was mostly Catholic, and the partner at first intercourse was also 15- 19 years of age.

Conclusion

Our study improved on the profile and experience of sexuality of a university population in southern Brazil by including a distinction between subgroups that allowed for more detail. This distinction may assist in the definition of the actions to be implemented for the profile and experience of sexuality of this population.

Abstract

This paper presents an evaluation of the accuracy of the Bayesian classifiers: Bayes Net, Naive Bayes and Averaged One-Dependence Estimator, to support diagnoses of osteopenia and osteoporosis. All classifiers showed good results, thus, given data, it is possible to produce a reasonably accurate estimate of the diagnosis.

Keywords:

Medical Informatics; Artificial Intelligence; Data Mining; Bayes Theorem; Osteoporosis.

Introduction

Osteoporosis is a disease that results in the decline in the health of the world population and challenges the public health and medical professions [1]. To address the uncertainty inherent in biomedical diagnoses, Bayesian classifiers, which are based on statistical models, have the advantage of determining the class to which a given record belongs compared to traditional classifiers, taking as base the probability of an element belonging to a class [2]. The Averaged One-Dependence Estimator (AODE) is considered an improvement on the Naive Bayes (NB) and an interesting alternative to other semi-naive approaches. It provides a good trade-off between efficiency and performance. Specifically, the AODE can be considered as an ensemble of SuperParent One-Dependence Estimators (SPODEs) because every attribute depends on the class and another shared attribute, which is designated as the superparent [3]. Thus, the diagnosis of diseases such as osteoporosis and osteopenia can become faster and precise. This paper presents an evaluation of the accuracy of the Bayesian classifiers Bayes Net (BN), NB and AODE to support the diagnosis of osteopenia and osteoporosis.

Methods

The database used in the experiments originated from a cross-sectional study involving 1871 women in southern Santa Catarina who were subjected to bone densitometry measurements under a specialized service from 2010 to 2012. This study was approved by the Ethics Committee under protocol 82939/2012. The experiments included the following steps: data cleaning and binarization; transformation of variables; selection tool; data mining; variable selection and use of classifiers. For validation was used a test set. Higher incidence of osteoporosis was presented among the 1871 women included in the sample.

Results

Approximately 300 rules were generated and selected for evaluation. Our results showed higher mean instances correctly classified using the Naive Bayes algorithm (82.84±14.42), and the average of incorrectly classified instances was higher for Bayes Net (17.46±14.76). The result for the kappa coefficient, related to the agreement between the result of the classifier and the result presented in the database by the specialist, was higher for the Bayes Net algorithm (0.33±0.29).

Conclusion

The development of this research includes the understanding that Bayesian classifiers use Bayes theorem, which allows them to stand out because of their efficiency, speed and accuracy, thus explaining its usefulness in the diagnosis process. Based on the results of analyzing statistical measures in the experiments described here (instances classified correctly and incorrectly, the kappa coefficient, mean absolute error, sensitivity, specificity, accuracy, recall, F-measure, and AUC), all classifiers showed good results, thus, given these data, it is possible to produce a reasonably accurate estimate of the diagnosis.

Trivalent Influenza Vaccine Adverse Event Analysis Based On MedDRA System Organ Classes Using VAERS Data

Cui Tao[a], Jingcheng Du[a], Yi Cai[b], Yong Chen[b]

[a] *School of Biomedical Informatics,* [b] *School of Public Health*
The University of Texas Health Science Center at Houston, TX, USA

Abstract

We studied serious reports following influnza vaccine from VAERS database in year 2011. Our statistical analyses revealed differences of reactions among different age groups and between genders. The results may lead to additional studies to uncover factors contributing to the individual differences in susceptibility to influenza infection.

Keywords:

Influnza vaccine adverse event, MedDRA, VAERS

Introduction

Seasonal influenza is a common vaccine-preventable disease with substantial morbidity. The social burden of seasonal flu can be substantial [1]. Annual vaccination is the most effective strategy to prevent influenza [2]. While their benefits far overweigh their risks and costs, influenza vaccines are accompanied with specific adverse events. Post-approval surveillance of vaccine adverse events is critically needed to assess the vaccine safety throughout its life on the market. The Vaccine Adverse Event Reporting System (VAERS) is a passive surveillance system to monitor vaccine safety after the administration of vaccines licensed in the United States [3]. In this study, we explored statistical analysis on annotated symptoms in the VAERS reports for patients with different genders and ages.

Materials and Methods

We searched the VAERS for US reports after Trivalent Influenza Vaccine (FLU3) in year 2011 and extracted serious reports (i.e., death, life-threatening illness, hospitalization, prolonged hospitalization, or permanent disability). For each report, the VAERS provides annotations for post-vaccination symptoms in Medical Dictionary for Regulatory Activities (MedDRA) terms [4]. To faciliate further statistical analysis, we further grouped these symptoms based on the MedDRA System Organ Class (SOC) using the NCBO Web Services [5].

To model the total number of serious symptoms per subject, we fit a zero-truncated Poisson regression on age groups and gender because a subject has to have at least one symptom to be included in the VAERS database. To study the risks of having serious symptom for each SOC type, we use logistic regression on age groups and gender.

Results

During the study period, VAERS received 7986 FLU3 reports, 638 were serious. Out of the 638 reports, 324 were for female patients, 295 were for male patients, and 134 , 156, 110, 185 were for patients in age groups 0.5-17, 17-49, 49-64, and >64 repectively. 5407 symptoms were grouped into 26 SOCs. The most frequent SOCs in the 638 reports are nervous system disorders, general disorders, and administration site condition and investigations.

Analysis using zero-truncated Poisson model indicated that the avarage number of symptoms per subjects in the study cohort is 8.74 (95% CI 6.76, 10.73). There are statistically significant differences in number of symptoms among four age groups and between different genders. The youngest age group (0.5 - 17 years) has the smallest number of symptoms per year, followed by age group 2 (17-49), age group 4 (>64), and finally age group 3 (49 – 64). The average number of symptoms for subjects of 17-49 years old is 13% higher than the average number of symptoms for subjects of 0.5-17 years old with the same gender (p=0.003).

Conclusion

This poster reports our preliminary analyses on influenza vaccine adverse events using VAERS data and MedDRA SOCs, which revealed differences of reactions among different age groups and between genders. The results may lead to additional studies to uncover factors contributing to the individual differences in susceptibility to influenza infection.

Temporal Relation Extraction in Outcome Variances of Clinical Pathways

Takanori Yamashita[a, b], Yoshifumi Wakata[a], Satoshi Hamai[c], Yasuharu Nakashima[c], Yukihide Iwamoto[c], Brendan Franagan[b], Naoki Nakashima[a], Sachio Hirokawa[d]

Abstract

Recently the clinical pathway has progressed with digitalization and the analysis of activity. There are many previous studies on the clinical pathway but not many feed directly into medical practice. We constructed a mind map system that applies the spanning tree. This system can visualize temporal relations in outcome variances, and indicate outcomes that affect long-term hospitalization.

Keywords:
Clinical pathway; Mind map; Hip replacement arthroplasty; Spanning Tree.

Introduction

Recently the clinical pathway has progressed with digitalization and the analysis of activity. There are many previous studies on the clinical pathway but not many feed directly into medical practice. The evaluation of temporal similarity among workflows has been reported, but they could not evaluate the medical process [1]. In this paper we visualize the temporal relations in outcome variances of the hip replacement arthroplasty clinical pathway and propose factors that affect long-term hospitalization.

Methods

A search engine was constructed from the outcomes of patients that were evaluated from admission to discharge. The patient's postoperative hospitalization days (POD) was also added as an attribute. If the POD search condition $\boldsymbol{q}$ is given, it will search for a list of patients with a POD longer than $\boldsymbol{q}$. In [2], the relationship of factors was visualized through combining generality and similarity by applying the spanning tree algorithm. We constructed a mind map system based on this method that can visualize the relationship of common attributes.

First, all of the outcomes that appear in the search results are sorted in lexicographic order of similarity and POD, and the top $\boldsymbol{K}$ outcomes $(\boldsymbol{o})$ with days $(\boldsymbol{d})$ $\{\boldsymbol{od_1}, \boldsymbol{od_2}, ..., \boldsymbol{od_K}\}$ are extracted. Second, the similarity of $\boldsymbol{o}$ and $\boldsymbol{q}$ represented by $\boldsymbol{sim(q, o)}$ was evaluated by the Jaccard index. Further, $\boldsymbol{sim(q, o_1) < sim(q, o_2)}$ is defined as (1) or (2).

$$sim(q, o_1) < sim(q, o_2) \quad (1)$$

$$sim(q, o_1) = sim(q, o_2) \quad \wedge \quad d_1 < d_2 \quad (2)$$

Then the tree will expand in the order of $\boldsymbol{od_2}, \boldsymbol{od_3}, \ldots,$ with $\boldsymbol{od_1}$ as the root of the tree. When a tree that contains the outcomes to $\boldsymbol{od_{(i-1)}}$ is obtained, the node $\boldsymbol{od_{(i)}}$ is connected to the node with the greatest similarity in $\boldsymbol{od_1}, \ldots, \boldsymbol{od_{(i-1)}}$ (Figure 1).

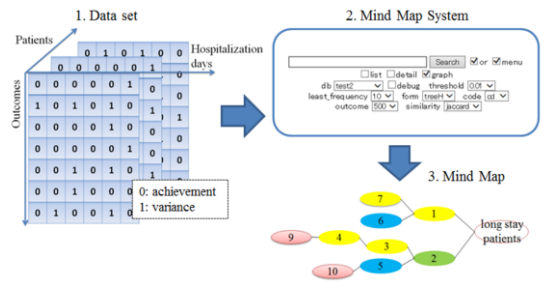

Figure 1 – Process of analysis in mind map system

Conclusion

A mind map system was used to extract the strong relations of outcome variances that have a significant influence on long-term hospitalization in hip replacement arthroplasty. Four outcomes of this case–respiratory stability, no problem in wounded area, pain control, and circulation stability–were suggested as possible critical indicators of medical process.

Proof of Concept HTML5 Webapp: Type 2 Diabetes risk stratification

Simon Lebech Cichosz[a] , Mette Dencker Johansen[a], Ole Hejlesen[a]

[a] *Department of Health Science and Technology, Aalborg University, Denmark.*

Abstract

Proof of concept HTML5 webapp for use in a diabetes screening context is presented.

Keywords:

HTML5; Webapp; Diabetes.

Introduction

Screening entire populations for type 2 diabetes is not cost-effective. Hence, an efficient screening process must select those people who are at high risk for diabetes. Risk stratification models have a substantial potential to be utilized in a screening context in order to identify high risk individuals who would subsequently undergo testing for diabetes [1, 2]. However, making such models available to the clinician is not a trivial task; they need to be easy to learn, use, and understand. Here we present a possible implementation of a risk stratification tool.

Methods

HTML5 and Javascript were used to create web apps compatible with most devices, and the apps can perform complex computations. This allows for location-independent use that can utilize internet connection whe possible and fall back to off line use if needed. This platform also makes it very easy to update content and information.

Results

We developed a proof of concept web app named DIRICA (Diabetes Risk Calculator) for use in risk stratification of potential diabetic patients in a screening context. The web app was tested on several devices (iPhone, iPad, Windows Phone, Android), as seen in Figure 1.

Conclusion

The web app has the potential to make clinical decision support systems for diabetes screening available globally with fast and easy content update. Further versions of the web app could also be used for information collection purposes.

Design of a Graph-Based System for Similar Case Retrieval of Pulmonary Nodules

José Raniery Ferreira Junior[a], Marcelo Costa Oliveira[a], Paulo Mazzoncini de Azevedo-Marques[b]

[a] *University Hospital (HUPAA/EBSERH), Institute of Computing, Federal University of Alagoas, Maceió, Alagoas, Brazil*
[b] *Internal Medicine Department, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, São Paulo, Brazil*

Abstract

Due to difficulty of diagnosing lung cancer, it is important to integrate computational tools in the imaging interpretation process. Content-Based Image Retrieval (CBIR) can provide decision support to specialists by allowing them to find nodules from a database that are similar to a reference one. However, CBIR systems still face problems visualizing multidimensional images. This paper presents the design of a graph-based system for the retrieval of similar temporal computed tomography (CT) scans of pulmonary nodules, in order to optimize the visualization of multidimensional images in a CBIR system. Temporal Image Registration has been used to compare reference and retrieved previously segmented nodules. A rooted tree graph is employed to visualize retrieved cases, and it is deployed in a web system for portability and usability purposes.

Keywords:
Pulmonary nodule; image retrieval; multidimensional data.

Introduction

Pulmonary nodules are the most common manifestation of lung cancer, the most deadly of all cancers [1]. Lung cancer diagnosis is a challenging task, even for qualified specialists [2]. Furthermore, for the early diagnosis of lung cancer, it is important to measure accurately the change in size, edge and texture of pulmonary nodules from two time-separated CT scans [1]. In order to aid specialists in the diagnosis of lung cancer, it is interesting to integrate the computer-based assistance to the imaging interpretation process. CBIR can provide computer-aided diagnostic support by allowing radiologists to find images from a database that are similar to the images they are interpreting [2]. However, there has been limited investigation into visualization methods for CBIR systems. An effective method of showing the images to the user is a critical aspect for such systems [3]. The goal of this paper is to present the design of a multiplatform visualization CBIR system, for the retrieval of similar multidimensional images of pulmonary nodules in temporal CT scans, using a horizontal-oriented rooted-tree-based graph approach.

Materials and Methods

The CBIR algorithm was initially implemented by *Oliviera and Ferreira* [2]. The temporal image database developed for this work is composed by CT lung scans with nodules ≥ 4 mm, with at least 2 time-separated scans. Each nodule of this database is described in four dimensions (x, y, z, t) and will be automatically detected and segmented. After the user selects the reference case, the system performs the similarity analysis, through Temporal Image Registration, and retrieves the most similar cases, according to Mutual Information metrics. The user can define the number of cases to retrieve. The system displays the most similar cases using a horizontal-oriented rooted-tree-based graph. A regular rooted tree is disposed in a vertical orientation, but for visualization purposes, the tree is presented horizontally. The proposed system is being developed with the multiplatform frameworks *HTML5*, *Java* and *D3.js* for platform portability and user usability purposes.

Results and Conclusions

The root of the displayed tree is the reference case and its height is 3 (Figure 1). In the first level, each vertex of the tree represents a similar case. The higher the vertex is, the more similar the case is. Users can select one vertex, using a mouse click, to see temporal samples. By clicking a similar case vertex, it expands and the tree reaches to the second level. The second level vertices are the temporal samples. By clicking a temporal sample vertex, it expands and the tree reaches to the third level. The third level vertices are the CT scans with segmented nodules. We expect that the visualization of retrieved similar cases of pulmonary nodules can be improved by the rooted-tree-based graph, and that temporal CBIR visualization systems will employ our approach in their end-user tools.

Abstract

After the Great East Japan Earthquake we constructed a community health care information network system. Focusing on the authentication server and portal server capable of SAML&ID-WSF, we proposed an audit trail management system to look over audit events in a comprehensive manner. Through implementation and experimentation, we verified the effectiveness of our proposed audit trail management system.

Keywords:
Audit Trail; Log Management; Visualization

Introduction

After the Great East Japan Earthquake, with the financial aid of the government, we constructed a community health care information network system. Currently more than 500 medical institutions have participated in this project. Medical records of 2.3 million residents will be collected in the future. To maintain a high level of security of this system and audit of the user/system operations trail, establishing a comprehensive audit trail management system is imperative. Since each system usually manages logs according to vendors or packages, it is extremely difficult to integrate audit logs among the systems in a unified way. In this paper, focusing on a central authentication server and a portal server capable of SAML&ID-WSF, we propose an audit trail management system to track audit logs of all the systems in a comprehensive manner. Through experimentation, we evaluate the proposed audit trail management system.

Methods

The community health care information network system consists of an authentication server, a portal system, and sub-system; such as two kinds of medical record viewers, two kinds of ASP electronic health record systems, a pharmaceutical care system, a portable electronic health record system etc. Each sub-system had already implemented the function to output audit logs in a different format making it unrealistic to force all the systems to output audit logs into a similar standardized format[1][2]. To build an audit trail management system tracing the audit events among systems in an appropriate manner, we focused on the fact that audit events occur when SAML&ID-WSF messages are exchanged between each systems. In fact, our systems were implemented with SAML&ID-WSF protocols. When needed an authentication server and a portal server communicate with sub-systems to provide the rights to access ticket by SAML and necessary attributes of users/patients by ID-WSF. Authentication proxy servers are introduced to talk SAML&ID-WSF with the authentication server instead of sub-systems. The proxy server can gather appropriate audit logs without modifying the sub-system. Logs are gathered only from the authentication server, proxy servers and portal server according to format[2]. Their logs contain the events of access/search of personal information and authentication. Then these logs are converted into a normalized structure to look over audit events of all the systems in a comprehensive manner, and stored into the structured database. To prevent falsification, logs are also archived with an electronic signature. Querying the structured database, audit events can easily be searched and analyzed through the web interface.

Results

We developed an audit trail management system with tomcat and apache solr. Logs for sub-systems were integrated into a structured database. Audit events of access/search of personal information and authentication can be analyzed according to sub-system, user/patient, and period. Additionally, statistical information of the system can be visualized. Since this system can be achieved solely with the modifications of the authentication server, proxy servers, and portal server, it is easy to extend this audit trail management system cost-effectively.

Conclusion

We proposed an audit trail management system by tracking authentication logs. Since this system has been implemented, very recently,we were only able to evaluate the functions of the proposed system. In the future, we will discuss the effectiveness and possible limitations through practical operation.

Abstract

Periodontal disease is a major cause for tooth loss and adversely affects individuals' oral health and quality of life. Research shows its potential association with systemic diseases like diabetes and cardiovascular disease, and social habits such as smoking. This study explores mining potential risk factors from dental electronic health records to predict and display patients' contextualized risk for periodontal disease. We retrieved relevant risk factors from structured and unstructured data on 2,370 patients who underwent comprehensive oral examinations at the Indiana University School of Dentistry, Indianapolis, IN, USA. Predicting overall risk and displaying relationships between risk factors and their influence on the patient's oral and general health can be a powerful educational and disease management tool for patients and clinicians at the point of care.

Keywords:
Periodontal disease; diabetes; smoking; risk factors; risk prediction; dental electronic health records.

Introduction

Periodontal disease (PD) is a significant oral health challenge, with almost half of all US adults aged 30 years and older (65 million adults) diagnosed or at risk for the disease [1]. Several systemic conditions and social behaviors such as diabetes and smoking are major risk factors for PD. Numerious risk assessment approaches identify patients at risk for PD. However, they face multiple barriers such as duplicate data entry and insufficient explanation of the risk factor's influence on PD status. Increasing HER adoption in dental practices and availability of detailed, patient data offers an opportunity to explore risk prediction for PD [2]. In this study, we explore mining selected risk factors from a dental EHR to create a preliminary risk prediction model for periodontal disease.

Methods

Our data set contains 2,370 individuals, 18 years and older, who underwent a comprehensive dental care examination (CDT code - D0150) between January 1, 2011 and January 1, 2012 from the dental EHR implemented at the Indiana University School of Dentistry, Indianapolis, IN, USA. The data included demographics, medical and dental history, social history, oral findings, treatment history, diagnosis, and treatment planning in a structured or free-text format. We extracted the known risk factors for PD from a subset of 200 randomly selected patients. For free text data, we built regular expressions for the keywords used by the providers to document a condition and converted free text into discrete values (present = 1, absent = 0), with manual comparison for accuracy. A novel risk prediction and visualization tool from prior research was applied to assess contextualized PD risk of an individual that combined dimensionality reduction, LDA-based classification and risk factor visualization [3].

Results

We retrieved risk factors of demographics, insurance, poor oral hygiene, bone loss information, vertical bone lesions, furcation involvement, subgingival restorations and calculus, deepest pocket depth, bleeding on probing, smoking, and diabetes. The accuracy with automated data was 92%, recall was 73% and precision was 93%. The precision was low for poor oral hygiene, furcation involvement, localized bone loss and subgingival calculus. Implicit keywords were missed in regular expressions such as bacterial plaque and calculus for poor oral hygiene and bone loss in a particular region for localized bone loss, resulting in low recall. The risk prediction and visualization method predicted 1,076 patients to be at high risk, with bone loss and demographic factors to be prominent risk drivers in this population. Ongoing analysis examines factor combinations to predict PD risk for the population and individual.

Conclusion

The risk assessment approach developed in this research has the potential to visualize and address the risk factors influencing a patients' PD as well as underlying systemic conditions at the point of care.

Distributed Parallel Computing in Data Analysis of Osteoporosis

Priscyla Waleska Simões[a,b], Ramon Venson[a], Eros Comunello[c], Rogério Antônio Casagrande[a], Everson Bigaton[a], Lucas da Silva Carlessi[a], Maria Inês da Rosa[b], Paulo João Martins[a]

Abstract

This research aimed to compare the performance of two models of load balancing (Proportional and Autotuned algorithms) of the JPPF platform in the processing of data mining from a database with osteoporosis and osteopenia. When performing the analysis of execution times, it was observed that the Proportional algorithm performed better in all cases.

Keywords:

Computer Communication Networks; Computational Clusters; Medical Informatics; Osteoporosis.

Introduction

One of the techniques for processing highly complex applications is through the building of computer clusters [1]. Furthermore, osteoporosis (OP) has become a public health problem that affects people worldwide [2]. An aging population contributes significantly to the understanding of why the disease has become increasingly important in view of increased life expectancies [2]. In this context, this research presents the performance evaluation of two algorithms for load balancing of the Java Parallel Processing Framework platform (JPPF) for clustering a medical database containing data on osteoporosis and osteopenia.

Methods

Applied and technological study. The experiments were performed from a database derived from a cross-sectional study that included 1871 women undergoing bone densitometry in southern Brazil (approved by the Research Ethics Committee under protocol 82939/2012).

The following variables were considered in the experiments: age bracket, previous fracture, number of previous fractures, previous fracture in the femoral neck, prior spine fracture, previous fracture in the forearm, previous fracture in the rib, use of drugs, menopause, use of calcium, hormone replacement therapy, use of drugs for the thyroid, hysterectomy, oophorectomy, diagnosis, body mass index (BMI), weight, and three degrees of obesity.

The load-balancing algorithms, Proportional (considered deterministic and adaptive), and Autotuned (heuristic algorithm based on Monte Carlo method), were used.

Results

The database was replicated in exponential growth to 478,976 records, generating nine scenarios. The tests were performed 30 times in each scenario and algorithm, in order to observe the growth of the asymptotic application, considering two, four, and eight nodes to compose the cluster. The model demonstrated that the Proportional balancing algorithm obtained better performance in all tests. However, the Autotuned balancing strategy showed a reduction in the response time when applied to the scenario of processing eight nodes, unlike what was observed with the Proportional strategy.

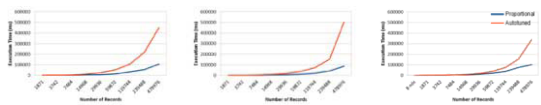

Figure 1 - 2 nodes (a), 4 nodes (b), 8 nodes (c)

Conclusion

Although the Proportional load balancing algorithm has shown superior performance in the data analysis of osteoporosis and osteopenia in all tested scenarios, this difference was minimized using a larger number of nodes, which suggests that their use can achieve the same performance or even outperform the other algorithm when used with an even larger number of processing nodes.

Thus, the next step of this project will be mining, considering the profile associated with osteoporosis and osteopenia, in a distributed environment by the Proportional algorithm.

Kmer-indexer: A Fast K-mer Indexing Program

Wang Xiaolei[a], Qu Wubin[b], Zhang Chenggang[b], Zhao Dongsheng[a]

[a] *Institute of Health Service and Medical Information, Academy of Military Medical Sciences, Beijing, China*
[b] *Beijing Institute of Radiation Medicine, State Key Laboratory of Proteomics, Beijing, China*

Abstract

In our previous work, a k-mer based program named MFEprimer-2.0 was designed and developed for primer specificity evaluation task. In order to increase the index processing speed, decrease the index data size and memory usage, we developed a new program named kmer-indexer. Compared to MFEprimer-2.0, the processing speed of kmer-indexer is 10+ times faster, the index data size can be significantly reduced to one third, and the memory usage is controlled within a small range so that this program can run on an ordinary PC.

Keywords:
PCR, primer, k-mer, index.

Introduction

In MFEprimer-2.0, we use k = 9 and a sliding window size = 1 bp to index the genome DNA and cDNA. The value of k can be changed based on the specific need of the user. But there are several problems when indexing the genome database. First, the indexing speed is very slow. Second, the volume of index is very large. To address these problems, we developed a new program named kmer-indexer written in c-language.

Methods

Algorithm and Procedures

The core algorithm of kmer-indexer splits the genome database file into gene segment. Later, the kmer-indexer iterates over the segments to find the positions of all k-mers in every gene.

Table 1 – The Kmer-indexer Algorithm

Algorithm 1.The kmer-indexer algorithm

1. Input: the sequence file Seq, k-mer length K;
   Output: the database INDEX_DB;
2. Preprocess Seq to get the number of genes N, and the gene segment string $\{S_0 \ldots S_{N-1}\}$;
3. The amount of $\{Kmers_0 \ldots Kmers_{M-1}\}$ with length of K is M=4**K, transform each k-mer to quaternary numeral system integer H;
4. Initialize containers $\{Queue_0 \ldots Queue_{M-1}\}$ to store position of each k-mer
5. for each S_i in $\{S_0 \ldots S_{N-1}\}$ do
6. Traverse each S_i to find all k-mers and their Pos, save Pos into cache file
7. for each $Queue_i$ in $\{Queue_0 \ldots Queue_{M-1}\}$
8. for each Pos_j in $\{Pos_0 \ldots Pos_N\}$ do
9. append position of each k-mer in Pos_j into $Queue_i$
10. insert $Queue_i$ into INDEX_DB

Data Structure

There are M=4**K different k-mers. We construct a hash table with m elements in memory, and use a hash function H(kmer) to transform each k-mer to a quaternary numeral system integer H. The integer is equal to the subscript of the corresponding element. We initialize each element in the hash table to a container for saving positions pos of k-mers on the gene and the serial number num of this gene (Figure 1).

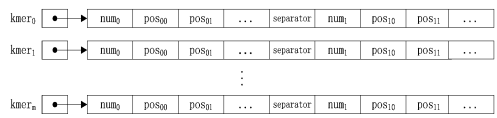

Figure 1 – The data structure of container

Results

The program was tested on a single server with two 64-bit x86 Intel Xeon E5620 4-core CPUs, 2TB 7.2K RPM SATA disk and 48GB RAM. The operating system is Red Hat Enterprise Server 5.7 using linux kernel version 2.6.18.

In order to evaluate the performance of kmer-indexer, we test five genome datasets in FASTA format (Table 2).

Table 2 – The Test Results

Dataset	Size (MB)	Running time(s)		Index data size(MB)	
		kmer-indexer	MFEprimer-2.0	kmer-indexer	MFEprimer-2.0

Cohort Discovery Query Optimization via Computable Controlled Vocabulary Versioning

Todd A Ferris[a] and Tanya Podchiyska[a]

[a] *Stanford Center for Clinical Informatics, Stanford University, Stanford, CA, US*

Abstract

Self-service cohort discovery tools strive to provide intuitive interfaces to large Clinical Data Warehouses that contain extensive historic information. In those tools, controlled vocabulary (e.g., ICD-9-CM, CPT) coded clinical information is often the main search criteria used because of its ubiquity in billing processes. These tools generally require a researcher to pick specific terms from the controlled vocabulary. However, controlled vocabularies evolve over time as medical knowledge changes and can even be replaced with new versions (e.g., ICD-9 to ICD-10). These tools generally only display the current version of the controlled vocabulary. Researchers should not be expected to understand the underlying controlled vocabulary versioning issues. We propose a computable controlled vocabulary versioning system that allows cohort discovery tools to automatically expand queries to account for terminology changes.

Keywords:

Information Storage and Retrieval; Vocabulary, controlled.

Introduction

Institutions that have enterprise Clinical Data Warehouses (CDW) frequently provide "cohort discovery" tools – self-service search systems for the CDW intended to allow a researcher to identify a collection of individuals that meet certain criteria that they specify. In the United States, patient diagnoses and procedures are coded for billing purposes using International Classification of Diseases (ICD-9-CM) and Current Procedural Terminology (CPT). Thus, these controlled vocabularies are heavily leveraged by researchers for cohort discovery tasks. In the STRIDE system, coded diagnoses and procedures are available for the past twenty years [1]. This is seen as a great benefit to researchers looking to identify large cohorts of patients.

However, there is a risk in using historic coded data because the meaning of codes changes over time as the understanding of disease evolves and the coding systems are updated to reflect that. Most clinical enterprises have a process in place to incorporate these updates that ensure the enterprise properly uses the new codes and accounts for refinements in meaning in existing codes. It has been the authors' experience that research CDWs do not have formal mechanisms in place to handle the controlled terminology changes and the impact the changes can have on cohort discovery. This poster describes an approach we took to represent code changes over time and translate them into query expansion.

Methods

A self-service cohort discovery tool should have the ability to detect that a term has undergone a change in meaning during the timeframe the researcher is interested in and to automatically include the terms relevant to the time period being searched. Thus the query tool needs access to a computable version history for each controlled terminology system in use.

We developed a computable representation of code changes in ICD-9-CM, including start and end dates for changed codes and pointers to substitution codes with broader or narrower meaning in order to support automatic query expansion. Through this approach, a search for patients with "venous embolism and thrombosis of deep vessels of lower extremity" automatically translates into a search for patients coded with leaf nodes of the respectively termed ICD-9-CM code 453.4 through the year 2009 as well as with child codes of the version of code 453.4 restated in 2010 as acute DVT and of the introduced in 2010 code 453.5 for chronic DVT.

Results

The STRIDE team has manually tracked versioning information in ICD-9-CM and CPT for the last 3 years. The team reviews updates in each ICD and CPT release and translates them into our internal representation of version difference. At this time, comparisons of the advantages and disadvantages of storing this information as RDF versus XML are underway. The research team has been leveraging the user base of the STRIDE cohort discovery tool to better understand the difficulties researchers face. Currently many searches require personal mediation by an informatics consultation specialist. Some of the most common issues impacting cohort identification are a lack of understanding of terminology-specific definitions, such as those for ICD-9-CM V, E, and not otherwise specified codes, as well as limited awareness of the variety of codes that could be used.

Acknowledgments

Supported by a NIH CTSA award – number UL1 RR025744.

A Statistical Analysis of Term Occurrences in Radiology Reporting

Yi Hong[a], Jin Zhang[b], Ying Zhu[b], Xiaoying Zhou[c]

[a] *Department of Product Engineering, MedeAnalytics, Inc., Emeryville, CA, USA*
[b] *School of Information Studies, University of Wisconsin-Milwaukee, WI, USA*
[c] *School of Information Resource Management, Renmin University of China, Beijing, China*

Abstract

To compare term occurrences in free-text radiology reports and RSNA reporting templates, we selected five templates from an RSNA reporting template library and their corresponding free-text reports as a test set, and employed the Wilcoxon signed-rank test to find out whether the terms in RSNA reporting templates match those terms appearing in corresponding free-text radiology reports. The results show that most terms in free-text radiology reports are covered by RSNA reporting templates. By assessing the terminology coverage of existing templates, this study may benefit the growth of the RSNA reporting template library.

Keywords:

Radiology reports, Reporting templates, Term occurrences, Wilcoxon signed-rank test.

Introduction

Free-text radiology reports have some inherent shortcomings, such as ambiguity and inconsistency of using common terms. Structured reporting may facilitate clear communication and significantly enhance readability and quality [1]. The Radiological Society of North America (RSNA) has developed a freely accessible online library of reporting templates (http://www.radreport.org) to promote structured radiology reporting [2]. As of April 2015, 269 reporting templates have been released to the template library. The elements of the templates have been mapped to corresponding terms in standardized biomedical ontologies such as RadLex® and SNOMED CT®. To compare term occurrences in free-text radiology reports and RSNA reporting templates, the Wilcoxon signed-rank test was applied to investigate how much of the content of free-text reports is covered by the terms included in the RSNA reporting templates.

Methods

Research data were collected from the RSNA reporting template library and de-identified free-text radiology reports. Reports from common exam types such as CT Head, Chest X-ray, MR Spine, NM Bone Scan, and US Abdomen, and the corresponding reporting templates, were selected as samples to conduct this research. A set of the terms extracted from the free-text reports was compared with another set of the terms extracted from the RSNA reporting templates. Each term was associated with a raw frequency score that indicated how many times this term appeared in the sample data set. These raw frequency scores were normalized to minimize the negative impact of different sample sizes on the comparison results. The Wilcoxon test is summarized below:

- Create a pair of samples with raw frequency scores of each exam type from both RSNA reporting templates and free-text reports;
- Generate a ranked term list of reporting templates;
- Generate an original ranked term list of free-text reports;
- Generate an abridged ranked term list based on the ranked term list and original ranked term list;
- Form an integrated ranking list by combining the abridged ranked term list and ranked term list;
- Set a significance level (α=0.01) for the Wilcoxon test;
- Enter the integrated ranking list into the SPSS software and obtain results

Results

The test results show that most terms in RSNA reporting templates match the terms appearing in corresponding free-text radiology reports, and the terms in CT Head and DX Chest reporting templates match to relatively small percentages of the terms in free-text reports, while MR Spine, NM Bone Scan, and US Abdomen reporting templates capture more terms in free-text reports. We also found out that RadLex® terms in the reporting templates better cover the terms that occur frequently in free-text radiology reports.

Conclusion

The RSNA reporting templates cover most terms that occur in free-text radiology reports. By assessing the terminology coverage of existing templates, this study may benefit the growth of the RSNA reporting template library.

Is it Possible to Make Everyone Talk in the Same Language?

Maggie Lau[a], Vicky Fung[a], Dr N T Cheung[a], Austen Wong[a], Edward Tam[a], Andy Wai[a]

[a] *Health Informatics, Hospital Authority of Hong Kong*

Abstract

Speaking the same language is a vital pre-requisite in verbal communication. The same applies in sharing health information among medical professionals in rendering care to patients. The Hospital Authority of Hong Kong developed its own clinical vocabulary table (HACVT) for clinicians to document diagnoses and procedures directly in the Clinical Management System (CMS) since 1996. HACVT is referenced to international classifications and reference terminologies, with local terms added and is built according to the principles of terminology management [1]. This poster describes the process of data standardisation within the organisation in the past years to achieve data interoperability through different adoption methods of HACVT.

Keywords:
HACVT; Data standardisation; Data interoperability

Introduction

The Hospital Authority (HA) of Hong Kong, managing 43 public hospitals, started its computerisation journey in the early 1990s. Lots of standalone clinical systems were built to meet the demands of capturing clinical data. Diagnoses and procedures were reported in a diverse manner in these systems. This created a problem in data integration and in providing care takers a complete clinical picture of the patient due to information being scattered and in various formats. It was not reasonable to ask clinicians to report data over again in the CMS while such information already existed in other systems. In order to improve the situation, it was decided to promote the use of HACVT within the organisation as a standard language.

Methods

There are 3 methods of adoption of HACVT in diagnosis and procedure reporting within HA (Figure 1).

1. Direct adoption in which clinicians can search the content of HACVT for diagnoses and procedures via the search panel provided by the Search Service. Both keyword and code search are available. Individual specialties can build their own commonly used lists of diagnoses and procedures from HACVT to facilitate reporting.
2. Indirect adoption via clinically designed templates in which diagnosis and procedure terms from HACVT can be generated by the selection made in the clinical templates[2] and be recorded in CMS.
3. Indirect adoption via mapping of terms used in standalone specialty based systems, such as Obstetrics, Psychiatrics and Radiology capturing diagnoses and procedures for different purposes to HACVT.

Results

Health care providers welcomed the move of integrating diagnoses and procedures reported from various systems through the adoption methods of HACVT within HA. Information on diagnoses and procedures of a patient can be accessed from one single point in the CMS. This does not only faciliate patient care delivery and clinical workflow, without unnecessary duplicate reporting, but also helps in data retrieval for secondary use such as in research, disease surveillances, etc.

Conclusion

Valuable clinical information can only be shared among health care providers from different disciplines when the same language is being used.

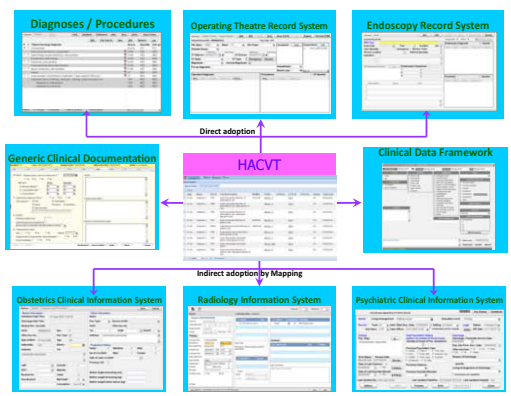

Figure 1 – Systems using HACVT for diagnosis and procedure reporting

A Novel Approach to Create a Machine Readable Concept Model for Validating SNOMED CT Concept Post-coordination

Marcelo Lopetegui[a, b], Alejandro Mauro[a]

[a] *Clínica Alemana de Santiago, Universidad del Desarrollo, Facultad de Medicina Clínica Alemana, Santiago, Chile*
[b] *Department of Biomedical Informatics, The Ohio State University, Columbus, OH, USA*

Abstract

Post-coordination provides the means to achieve an appropriate content coverage, which is critical in successfully adopting clinical reference terminologies, and thus represent clinical information consistently. However, one of the major problems of post-coordination corresponds with ensuring only clinically sensible concepts can be constructed. In this poster, we present the development of a novel approach to generate a MRCM computationally, in order to facilitate the adherence to the existing guidelines and improve the quality of post-coordination in SNOMED CT.

Keywords:

SNOMED CT; Post-coordination Validation; Standardization.

Introduction

Post-coordination workflow includes 3 steps: a) to select the source-concept being modeled; b) to select an attribute as the relationship type (i.e. laterality, clinical course); and c) to select a target concept for the attribute value (i.e. right/left, acute/chronic). Without an appropriate concept model, this could lead to meaningless relationships (i.e. a PROCEDURE having 'laterality' of ACUTE). SNOMED CT, the most comprehensive and internationally validated clinical terminology, includes guidelines for post-coordination, developed by the International Health Terminology Standards Organization (IHTSDO). However, a lack of adherence has been reported as the most frequent reason for classification failure[1]. We hypothesize that a contributing factor to this lack of adherence corresponds to the difficulties of implementing the current concept model, since it is only available as unstructured text. Previous studies proposed models for representing the concept model, but require a manual data entry[2].

Methods

We present our algorithm that reasons upon actively defining relationships in any given snapshot of SNOMED CT, and systematizes the detection and import of the allowable attributes for specific domains and the allowable ranges for specific attributes, automatically generating the rules. This approach relies on the assumption that pre-coordinated concepts respect the rules in the Editorial Guide of SNOMED CT.

Results

Allowable attribute types by top-level hierarchy. Based on the July 2014 SNOMED CT RF2 snapshot, our algorithm correctly inferred 61 out of the 66 rules. The five missed allowable attributes corresponded to '*Episodicity'* and '*Severity'* for CLINICAL FINDINGS, '*After'* for EVENTS, '*Has dose form'* for PHYSICAL OBJECTS, and '*Time aspect'* for PROCEDURES.

Allowable range by attribute type. Our approach was able to correctly generate 38 of the 40 rules for attributes where the allowable range corresponds to a single sub-hierarchy. The three missed rules correspond to the allowed range for the attributes '*Time Aspect*' (Descendants of TIME FRAME), '*Severity*' (Descendants of SEVERITIES) and '*Episodicity'* (Descendants of EPISODICITIES). When the expected allowable range included more than one sub-hierarchy, it correctly identified only 26 allowed ranges, missing 42, and wrongly stating 11. All wrongly stated ranges were close ancestors of the expected ranges.

Discussion

The high accuracy of our approach for listing the allowable attribute types for specific domains should be interpreted as a successful evaluation of SNOMED CT pre-coordination consistency and adherence to the Guidelines. However, by using the SNOMED CT RF2 as the only source to generate the MRCM, the algorithm misses knowledge concerning attributes reserved for post-coordination (i.e. the case with '*episodicity'* and '*severity*'). This low sensitivity of the generated MRCM jeopardizes the initial intent of completely automatizing the generation of the concept model.

Given the incomplete MRCM, we recommend complementing it by continuously consuming locally post-coordinated concepts. Thus, the newly generated knowledge-base could then be used as a decision support system for terminology coders, warning them whenever a type of attribute is being used for the first time for a given domain, or when a target concept is outside a previously used range. This approach respects locally defined rules and maintains consistency in future post-coordination.

Towards a Clinical Decision Support System for Drug Allergy Management: Are Existing Drug Reference Terminologies Sufficient for Identifying Substitutes and Cross-Reactants?

William Ogallo, Andrew S. Kanter

Department of Biomedical Informatics, Columbia University, New York, USA

Abstract

Drug allergy cross-reactivity checking is an important component of electronic health record systems. Currently, a single, open-source medication dictionary that can provide this function does not exist. In this study, we assessed the feasibility of using RxNorm and NDF-RT(National Drug File – Reference Terminology) for allergy management decision support. We evaluated the performance of using the Pharmacological Class, Mechanism of Action and Chemical Structure NDF-RT classifications in discriminating between safe and cross-reactive alternatives to a sample of common drug allergens. The positive predictive values for the three approaches were 96.3%, 99.3% and 96.2% respectively. The negative predictive values were 94.7%, 56.8% and 92.6%. Our findings suggest that in the absence of an established medication allergy classification system, using the Pharmacologic Class and Chemical Structure classifications in NDF-RT may still be effective for discriminating between safe and cross-reactive alternatives to potential allergens.

Keywords:

Drug Allergy; Terminology; Clinical Decision Support.

Introduction

A key function of a medication allergy decision support system is the ability to discriminate between the safe-to-use substitutes and cross-reactants of medication allergens. The NDF-RT (National Drug File – Reference Terminology) and RxNorm are two publicly available terminology standards for the electronic representation of drug information. The NDF-RT contains different hierarchies that are used to categorize medications [1]. RxNorm provides normalized names for clinical drug-related concepts [2]. In this study, we investigate the feasibility of using the two resources in identifying safe substitutes and cross-reactants of common drug allergens.

Methods

We identified the RxNorm ingredient concepts of twelve drugs: Aspirin, Atorvastatin, Cephalexin, Clarithromycin, Doxycycline, Enalapril, Enoxaparin, Ibuprofen, Losartan, Morphine, Penicillin G and Sulfasalazine. For each ingredient concept identified, we extracted the mappings to NDF-RT and generated the sets of ingredients with the same Indication, Pharmacologic Class, Mechanism of Action and Chemical Structure. Three set-theory-based criteria were applied to discriminate between safe and cross-reactive alternatives to the twelve ingredients studied. By the Pharmacologic Class criteria, the safe alternatives to an ingredient used for a particular indication was defined as the set of ingredients with the same Indication (A) but different Pharmacologic Class (B) i.e. $\{x \in A | x \notin B\}$. Conversely, cross-reactants were identified as the set of ingredients with the same Pharmacologic Class (B) i.e. $\{x \in B\}$. The same logic was applied to the Mechanism of Action and Chemical Structure criteria. We evaluated the ability of each criterion to correctly identify the sets of safe alternatives and cross-reactants against a gold standard derived from medical literature.

Results

The sensitivity, specificity, positive predictive value and negative predictive value of the three criteria are shown in Table 1. All three criteria had high positive predictive values, suggesting that they are good at correctly identifying true safe alternatives. The Pharmacologic Class and Chemical Structure criteria had high negative predictive values, suggesting that they may be good at correctly identifying true cross-reactants.

Table 1: Performance of Criteria used to discriminate between select safe (S) and cross-reactive (CR) medications

		Reference		% SEN	% SPE	% PPV	% NPV
		S	**CR**				
PC	S	988	38	99.5	70.1	96.3	94.7
	CR	5	89				
MOA	S	901	6	90.7	95.3	99.3	56.8
	CR	92	121				
CS	S	986	39	99.3	69.3	96.2	92.6
	CR	7	88				

S: Safe, CR: Cross-reactive, SEN : Sensitivity, SPE: Specificity, PPV : Positive Predictive Value, NPV: Negative Predictive, PC: Pharmacology Class, MOA: Mechanism of Action, CS: Chemical Structure

Conclusion

Our findings demonstrate the feasibility of using the NDF-RT and RxNorm to infer safe and cross-reactive medications in the absence of an established medication allergy classification system, with the caveat that a more generalizable approach would require additional curation. Different criteria may be selectively be applied to particular situations.

Consumer Health Vocabulary: A Proposal for a Brazilian Portuguese Language

Josceli Maria Tenório,[a] Ivan Torres Pisa[b]

[a] *Graduate Program in Management and Health Informatics, Universidade Federal de São Paulo, Brazil*
[b] *Health Informatics Department, Universidade Federal de São Paulo, Brazil*

Abstract

Studies show a gap between the expressions commonly used by health consumers and health professionals. To bridge this gap, consumer health vocabularies are presented as a solution. The aim of this paper is to describe an on-going project to create a consumer health vocabulary (CHV) in the Brazilian Portuguese language. This project will be developed in three phases: terms extraction and connection to compose a CHV graph structure, human validation, and computacional application development. We expect to make a CHV beta version (including approximately 5,000 valid consumer terms stored in a database graph) available. This project can contribute to the improvement of CHVs.

Keywords:
consumer health information; controlled vocabulary.

Introduction

Consumer health vocabularies (CHV) are defined as linking everyday words and phrases about health to technical terms or jargon used by health care professionals [1]. These tools are presented as a solution to a gap in communication between health consumers and health professionals, which hinders health information retrieval. Research to support consumer web searches for healthcare information is an important issue [2].

The aim of this paper is to describe the on-going project to create a CHV in the Brazilian Portuguese language. This CHV model proposes a vocabulary based on Semantic Web and linked open data concepts using W3C standards.

This study is part of academic activities at the research group Saúde 360º (360º Health saude360.com.br) regarding consumer health informatics, clinical decision support systems, e-health process and evaluation, ontology for health, knowledge discovery and data mining, and big data. The group is part of the Graduate Program in Management and Health Informatics, Federal University of São Paulo (UNIFESP), Brazil.

Materials and Methods

This CHV model will be developed based on three phases: automatic terms extraction and metadata connection to compose an initial CHV graph structure, human validation, and making the CHV available using a computacional application.

Phase 1—Extracting terms and connecting data: We will obtain the CHV model's terms using two distinct data source groups: open-structured data sources (e.g., health technical controlled vocabularies, such as the Unified Modeling Language System UMLS Portuguese version, DBPedia [pt.dbpedia.org], Wikipedia [wikipedia.org]), and texts focused on health consumers (e.g., published news with health subjects, RSS, and social media). In order to identify inedited terms, we will analyze the selected texts by applying techniques for extraction and automatic recognition of terms [3].

Phase 2—Human validation: The human efforts include the validation of the consumer terms list and their respective meanings. A specific survey will be developed and applied to obtain the health professionals' answers. The Delphi method will be applied to achieve an opinion convergence about a set of potential terms to compose this CHV model.

Phase 3—Computational application: In order to facilitate the data exchange, the search for health information, and integrating other projects, this CHV data will be stored in a standard model for data interchange on the web under the Resource Description Framework (w3.org/RDF). A computational application will be developed to support this model and made available to health consumers to access the contents.

Expected Results

The expected result is an available CHV beta version including approximately 5,000 valid consumer terms stored in a database graph. The idea is to connect semantically the consumer terms to technical terms and their meaning. Each consumer term will have a connection to a technical term, synonym, related term, and meaning.

Conclusion

This paper described the proposal to develop a CHV based on automatic data extraction from the web for Brazilian Portuguese language. Only the validation process will be based on human efforts, which could be very time consuming. We expect to obtain the CHV structure described in Phase 1 in the next year. This study can then contribute to the improvement of CHV development.

ICHI Categorial Structure: a WHO-FIC Tool for Semantic Interoperability of Procedures Classifications

Syed M. Aljunid[a,1] , Jean Marie Rodrigues[b], Linda Best[c], Zafar Ahmed[a], Hasrul Reeza Mustaffa[a] , Béatrice Trombert[b], Syed M. Hamzah Aljunid[a] , Julien Souvignet[b] and Sukil Kim[d]

[b] *INSERM U 1142 LIMICS Upmc and UP13 Paris, France*
[c] *University Of Sydney, Australia*
[d] *Catholic University of Korea, Korea*

Abstract

Casemix grouping using procedures classifications has become an important use case for health care terminologies. There are so many different national procedures classifications used for Casemix grouping that it is not possible to agree on a worldwide standard. ICHI (International Classification of Health Interventions) is proposing an approach that standardises only the terminologies' model structure. The poster shows the use of the ICHI alpha to replace ICD9 CM Volume 3 in the UNU-CBG International Casemix grouper.

Keywords:

Procedures Classifications; Casemix Grouper; ICD 9CM; ICHI.

Introduction

National case mix projects ***developed*** around the world ha***ve*** been facilitated by the use of WHO International Classification of Diseases (from ICD 8 to ICD 10 [1] and ICD 9 CM and ICD 10 AM. ***However, national case mix projects*** been hampered by the absence of an international classification of procedures**.**

Since 2006, the WHO-FIC Family Development Committee has been developing ICHI based on an ontology framework defined in ENISO 1828 named Categorial structure [2] and the UNU-CBG Casemix grouper has been developed at National University of Malaysia [3].

Materials and Methods

ICHI alpha is available at [4]. The coding scheme comprises a seven-character structure for the three axes and two semantic links.

The UNU-CBG Casemix system uses ICD-10 for diagnoses and ICD9-CM for procedure coding. The grouper also used WHO-Disability Assessment Scale (WHO-DAS) and 12-Item version 2.0 for evaluation of Activity of daily living.

Mapping was done in two steps. Lexical mappings and semantic mapping and comparative grouping is represented in a work flow figure named Mapping Process ICD9-CM to ICHI in UNU-CBG Casemix Grouper with two outputs to be compared.

Results

When OUTPUT I and OUTPUT 2 were compared, 31,703 out 34,978 cases (90.6%) produced the same Case-Based Group(CBG) codes. Two tables summarise and explain the differences.

Conclusion

The results challenge a basic statement of ICHI developers that ICHI alpha must be able to replace ICD 9 CM volume 3 because ICHI is less granular.

Acknowledgments

We acknowledge the WHO-FIC experts from Australia, Canada, China, France, Germany, Italy, Nordic European Countries and Thailand who did the lexical mapping.

National governance of archetypes in Norway

Silje Ljosland Bakke[a]

[a] *Bergen Hospital Trust and National ICT Hospital Trust, Bergen, Norway*

Abstract

Norwegian National ICT has implemented a national governance scheme for archetypes. The scheme uses openEHR, and is possibly the first of its kind worldwide. It introduces several new processes and methods for crowd sourcing clinician input. It has spent much of its first year establishing practical processes and recruiting clinicians, and only a few archetypes has been reviewed and approved. Some non-reusable archetypes have emerged while the governance scheme has established itself, which demonstrates the need for a centralised governance. As the mass of clinician involvement reached a critical point at the end of 2014, the rate of archetype review and approval increased.

Keywords:

Crowdsourcing; Registries; Informatics; Common Data Elements; Semantics; clinical data modelling; openEHR; archetypes; governance.

Introduction

The Norwegian hospital ICT collaboration trust, National ICT, has implemented a national governance scheme for archetypes.

Archetypes, also known as detailed clinical models, are small, reusable data model components. Each archetype contains the data elements and definitions necessary to record the structured documentation of a single clinical concept, for example “blood pressure” or “diagnosis”.

To ensure high quality, reusability and the possibility for semantic interoperability, archetypes must be developed collaboratively, and adopted only after a thorough review and approval process. The governance scheme provides the framework and tools to achieve these goals.

Methods

The national governance uses the openEHR specification, methodologies and tools for modelling archetypes.

The Norwegian national archetype governance is possibly the first of its kind worldwide. As such, it has had to invent many of the practicalities involved in such a scheme.

Requirements and priorities are defined by clinicians, vendors and registries, and the governance scheme does not interfere with initiatives’ development priorities; a so-called “do-ocracy”.

The governance scheme has introduced a national editorial board for archetypes, responsible for conducting and approving the review process of submitted archetypes. It defines the requirements for which groups of clinicians and others should take part in the review of each archetype. Clinicians are involved using organisation networking and crowd sourcing methods. Effective governance is heavily dependent on a common collaboration tool for designing, approving and making archetypes available.

Results

The editorial board was formally formed in January 2014, two full time positions have been created to coordinate the work of the editorial board, and the Norwegian Clinical Knowledge Manager (CKM) collaboration tool is available online. The CKM is a web-based tool for collaborative development, archetype reviews and library functions.

The first year of the governance scheme was spent establishing and streamlining the governance processes in practice, as well as recruiting clinicians for archetype reviews.

Relatively few archetypes were reviewed and approved during the first year, as clinician recruitment took longer than initially expected. During this time, some models of a non-reusable nature emerged as vendor and registry development moved on regardless.

At the end of 2014, the review and approval rate increased, and five of the six archetypes approved in the first year were approved in December. This coincided with an increased availability of clinicians for reviews.

Conclusion

Though limited in number, the emergence of some non-reusable archetypes during the first year clearly demonstrates the need for a centralised governance to achieve quality, reusablity and interoperability in clinical models.

Such a governance scheme needs to be transparent, agile, and have the resources to respond to requirements and initiatives from vendors, registries and clinicians alike.

With the increased rate of archetype review and approval experienced at the end of the first year, it seems that achieving a critical mass of involved clinicians is a key success factor.

Textual Definitions in the Leukemia Domain: Methodological Guidelines for Biomedical Ontologies

Amanda Damasceno de Souza[a], Maurício Barcellos Almeida[b]

[a] *School of Information Science, Federal University of Minas Gerais, Belo Horizonte, Brazil*
[b] *Advisor - Department of Theory and Management of Information - Federal University of Minas Gerais - Belo Horizonte, Brazil*

Abstract

The goal of our study is to establish methodological guidelines for the formulation of definitions in biomedical ontologies thatare not so common in the field of Library & Information Science.

Keywords:
Definitions; Biomedical Ontologies.

Introduction

In this study, we aim to develop a systematic process for creating definitions. The step we have taken can be considered as the general steps for creating definition, but we apply them in an ontology in the blood cancer domain, the leukemia domain in particular. In this poster, we discuss applied ontology principles in the construction of a fragment of a biomedical ontology, seeking to formulate textual and formal definitions for that field of cancer. This study is part of construction of the *Blood Ontology* (BLO), an ontology about blood. Ontologies provide clear and coherent definitions of structures found in reality, written in a form that is computer understandable. Consistency in definitions requires a unifying viewpoint. In order to make these definitions understandable for computers, one has to create textual definitions and then translate them to some formal logic. A good definition is fundamental for understanding the concepts, for the integration languages and makes them compatible [1].

Methods

The terminological sample was taken from BLO. We start defining a kind of acute myeloid leukemia (AML) that has 24 classes. We also intend to define other hematological neoplasms, namely, the Myelodysplastic syndrome with 5 classes and the Myeloproliferative neoplasm with 11 classes. We have a systematized criteria for writing natural language and formal logic language definitions based on the best practices proposed by Köhler et al. [2], Smith et al. [3] and Seppäla and Ruttenberg [4], to mention a few. At this moment, our research does not bring complete literature review, but only few references were adopted for testing the creation of a set of guidelines. The steps in formulating textual definitions are part of our preliminary results, organized in list as follows: a) separate the term; b) get a preliminary definition of the meaning of the term from any source; c) establish the highest genus in the context of use of the term; d) establish the essential characteristic that distinguish the genus from species; e) formulate the first version of the definition in the form S = Def. G which Ds, where "G" stands for genus, which is the parent of S; and "S" stands for species; f) check if the definition is a statement that satisfies the necessary and sufficient conditions; g) check principle of non-circularity; h) check the principle of multiple-inheritance. We don't believe we are contributing to the state of art ontological engineering, but we are making an effort to define some cases in our leukemia ontology. The main contribution of our approach is educational, and an attempt to propose an approach to people building ontologies in the field of Library & Information Science. In general we do not have guidelines to build good definitions [4].

Conclusion

This is an ongoing research project in the Information Science field. We present preliminary and partial results of our research, in the hope that soon we are able to define other types of leukemia.

A Pilot Study on Modeling of Diagnostic Criteria Using OWL and SWRL

Na Hong[a,b], Guoqian Jiang[a], Jyotishiman Pathak[a], Christopher G Chute[a]

[a] *Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA*
[b] *Institute of Medical Information, Chinese Academy of Medical Sciences, Beijing, China*

Abstract

The objective of this study is to describe our efforts in a pilot study on modeling diagnostic criteria using a Semantic Web-based approach. We reused the basic framework of the ICD-11 content model and refined it into an operational model in the Web Ontology Language (OWL). The refinement is based on a bottom-up analysis method, in which we analyzed data elements (including value sets) in a collection (n=20) of randomly selected diagnostic criteria. We also performed a case study to formalize rule logic in the diagnostic criteria of metabolic syndrome using the Semantic Web Rule Language (SWRL). The results demonstrated that it is feasible to use OWL and SWRL to formalize the diagnostic criteria knowledge, and to execute the rules through reasoning.

Keywords:

Diagnostic Criteria; Formalization; Rules; OWL; SWRL

Introduction

Standardization and computerization of diagnostic criteria is essential for automating clinical decision making. However, a principal challenge is the lack of an explicit and consistent information model for computable diagnostic criteria. Furthermore, formalizing the inner logic in diagnostic criteria is complex. Semantic Web technologies provide a homogeneous framework that enables an ontology-based modeling using the Web Ontology Language (OWL) and support rules authoring using the Semantic Web Rule Language (SWRL). The objective of this study is to describe our efforts in a pilot study on modeling diagnostic criteria using a Semantic Web-based approach.

Materials and Methods

We first identified a collection of diagnostic criteria from medical textbooks and the literature, and randomly selected 20 diagnostic criteria from different clinical subjects. Second, we manually annotated diagnostic criteria text with the ICD-11 content model [1] and analyzed the distribution of annotations. Third, we invoked the NCBO Bioportal Annotator to analyze the coverage in existing medical terminologies. Fourth, we refined the ICD-11 content model into an operational model using OWL representation. Finally, we performed a case study by manually generating a set of rules in SWRL for the dignostic criteria of metabolic syndrome. We used the Protégé SWRL plugin for rule editing and invoked Pellet as a rule engine to perform reasoning.

Results

Table 1 shows the distribution of data element annotations based on the ICD-11 content model. We found that Investigation Findings and Signs and Symptoms were the two most frequent annotations for data elements in the diagnostic criteria. Terminology coverage analysis using the NCBO BioPortal Annotator demonstrated that SNOMED CT and LOINC have the best coverage for the data element annotations.

Table 1 - Distribution of data element annotations based on ICD-11 Content Model

ICD-11 Content Model	Count	Examples
Investigation Findings	74	Serum triglycerides
Signs and Symptoms	69	Fatigue, Headache
Title	20	Metabolic Syndrome
Causal Properties	18	Pericardial effusion
Classification	12	T71
Severity of Subtype	10	Mind, Moderate, Severe
Body System/Structure	8	Nervous system
Specific Condition	3	Female, Pregnancy
Temporary Properties	2	Age 55, sudden

We constructed SWRL rules for the diagnostic criteria of metabolic syndrome. In total, we produced 21 individual SWRL rules for the criteria. For example, the following is a SWRL rule for the criterion - Waist circumference >102 cm in men. *Rule:Patient(?x), WaistCircum(?y), has_sex(?x, Male), has_result(?x, ?y), has_unit(?y, cm), has_value(?y, ?w), greaterThan(?w, 102) -> has_Evidence(?x, Con1)*. Based on these rules, we invoked Pellet to automatically allocate patients into target diagnosis coded in an ICD category.

Conclusion

In this pilot study, we demonstrated the feasibility of modeling diagnostic criteria using the ICD-11 content model and the terminology coverage of existing biomedical ontologies. We leveraged a Semantic Web-based approach. We believe this study will help future research on the development of formalized representations to capture diagnostic criteria and to enable computer reasoning. We also plan to test the utility of the rules using real-world patient data.

Constructing a Graph Database for Semantic Literature-Based Discovery

Dimitar Hristovski[a], Andrej Kastrin[b], Dejan Dinevski[c], Thomas C. Rindflesch[d]

[a] *Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*
[b] *Faculty of Information Studies, Novo mesto, Slovenia*
[c] *Faculty of Medicine, University of Maribor, Maribor, Slovenia*
[d] *National Library of Medicine, Bethesda, MD, USA*

Abstract

Literature-based discovery (LBD) generates discoveries, or hypotheses, by combining what is already known in the literature. Potential discoveries have the form of relations between biomedical concepts; for example, a drug may be determined to treat a disease other than the one for which it was intended. LBD views the knowledge in a domain as a network; a set of concepts along with the relations between them. As a starting point, we used SemMedDB, a database of semantic relations between biomedical concepts extracted with SemRep from Medline. SemMedDB is distributed as a MySQL relational database, which has some problems when dealing with network data. We transformed and uploaded SemMedDB into the Neo4j graph database, and implemented the basic LBD discovery algorithms with the Cypher query language. We conclude that storing the data needed for semantic LBD is more natural in a graph database. Also, implementing LBD discovery algorithms is conceptually simpler with a graph query language when compared with standard SQL.

Keywords:

Databases; Data Mining; Semantics; Literature Based Discovery.

Introduction

The goal of LBD is to generate novel hypotheses by analyzing the biomedical literature. For this project, biomedical concepts and relations between them were extracted from MEDLINE and stored as a network. It is common in LBD work to use concept co-occurrence as an indication of a relation between concepts. In this research, we used semantic relations instead of co-occurrences because semantic relations are more expressive and more likely to be real relations. As a source of semantic relations we used the Semantic MEDLINE Database (SemMedDB) which contains semantic relations extracted with the SemRep semantic interpreter (e.g. SemRep extracts the relation Ethionine-CAUSES-Lesion from the sentence "Ethionine can trigger lesions."). SemMedDB has relations from all of MEDLINE and is available as a MySQL database. MySQL is generally efficient, but modeling networks using a relational database causes a large number of many-to-many relations. Complex join queries are then needed to retrieve such data. Here we propose the Neo4j graph database as an alternative for implementing semantic LBD because Neo4j is particularly useful for storing data structured as a network.

Methods

We exported the semantic relation instances from SemMedDB in a text CSV format. We wanted to aggregate the instances into (concept1, relation, concept2, frequency) tuples where "frequency" is the total number of (concept1, relation, concept2) instances. First we tried to aggregate and load the data with the Neo4j "LOAD CSV", but this command was not able to load this amount of data. Then we tried to aggregate with several AWK scripts and to load the data into Neo4j with a stand alone batch importer. This approach worked out very well. Finally, we implemented a few LBD discovery patterns with the Cypher graph query language.

Results

Currently there are 269 047 unique concepts and 14 150 952 distinct relationships between them in the graph database. We show here how to implement the LBD discovery pattern "inhibit the cause of the disease" which can be used to find novel treatments. The idea of the discovery pattern is to find drugs that inhibit some genes that are etiologically related to a disease. Additionally, we are interested only in drugs that have not been already used to treat the disease. In this Cypher query, *phsu*, *gngm* and *dsyn* are UMLS semantic type abbreviations; and *drug*, *gene* and *disease* are variables that are instantiated to particular values when the query is run:

```
MATCH (drug:phsu) -[:INHIBITS]->
(gene:gngm) -[:CAUSES]-> (disease:dsyn)
WHERE NOT (drug)-[:TREATS]->(disease)
RETURN drug, gene, disease
```

Conclusion

Using a graph database such as Neo4j for storing the network data structure needed for semantic LBD is more natural and efficient than using a relational database.

Implementing discovery algorithms in the form of discovery patterns is conceptually easier and simpler when using a graph query language such as Cypher when compared to standard SQL.

Development of an Ontology to Recommend Exercises from Conceptual Maps

Márcia Ito[a], Débora Lina N. Ciriaco Pereira[a]

[a]*IBM Research, São Paulo, Brazil*

Abstract

The recommendation of exercise plans requires several variables to be considered (e.g., patient's conditions and preferences) and are normally complex to analyze. To facilitate this analysis we proposed the creation of an ontology to assist professionals to recommend exercises. We interviewed 2 experts and this resulted in IDEF diagram and conceptual map. The conceptual map proved to be the preferred way that experts gained more understanding compared with the IDEF diagram. In addition, we also used the conceptual map to validate the formal structure of experts' ideas. From the conceptual map we created an ontology that is being reviewed. After this, we plan to incorporate the ontology into a decision support system that will assist professionals to recommend exercises for their patients.

Keywords:
Biomedical ontologies; Exercise therapy; Medical informatics applications; Clinical decision support systems.

Introduction

The practice of physical exercise has been increasingly encouraged to prevent or aid treatment of chronic diseases. However, in order to have all the benefits, it is necessary for professionals to provide an exercise plan for the specific physical condition of each patient. For this, several variables should be considered. Considering all variables however, makes analysis complex [1]. Thus, we propose to establish a system to support professionals in development of exercise plans which consider both patients' conditions and preferences. Considering these aspects, we decided to develop an ontology to recommend exercises from conceptual maps. This ontology will compose the decision support system.

Materials and Methods

We interviewed 2 experts in the domain area in order to understand their mental models. Following these models, we defined a process of exercise recommendations. Initially, we tried to formalize the process in a flowchart but we realized that creating an IDEF[1] diagram and a conceptual map were better approaches to understand the existing mental models because we could relate concepts by linking words. The results were analyzed by the experts who recommended some adjustments. After this, an ontology was created using the CmapTools[2]. This method is increasingly used once the information has separate sources. Through this method, there results a set of concepts, with their associated relationships and instances which are concise and concrete; and useful for the construction of a decision support system [2].

Results

From the interview with the experts, we created one flowchart, an IDEF diagram and two conceptual maps. An ontology in OWL language was created from the final conceptual map. We formalized the knowledge represented in the conceptual map using an ontology. The tool allowed the creation of a tree that has the structure of the concepts. This tree initially had some inconsistencies and revisions were made in order to improve the ontology.

Discussion and Conclusion

The experts' interviews demonstrated that human knowledge is not structured, and its expression is not a simple task. To structure and express this knowledge, we used several tools. The flowchart proved to be restricted, whereas the IDEF diagram was very technical. On the other hand, the conceptual map proved to be a very useful tool both to structure and validate the mental models of the experts. To build the conceptual map we had to understand the concepts, their connections and interrelations. It was necessary to be careful about linking words so they could eventually give rise to the formal ontology. It was necessary to standardize the terms between both experts; and between the experts and us so we could use the patterns that we had in this area. Even after adjustments in the concept map, the ontology that was generated in a tree format allowed us to recognize problems in the expression of ideas. This demonstrates the need for revisions in the ontology before implementing it in a decision support system.

Acknowledgments

We thank Juliana Batista and Dr. Mauro Vaisberg, the experts who helped us with the plan of exercises.

Utility of Arden Syntax for Representation of Fuzzy Logic in Clinical Quality Measures

Robert A. Jenders

Center for Biomedical Informatics & Department of Medicine, Charles Drew University, Los Angeles, CA, USA
Department of Medicine, University of California, Los Angeles, CA, USA

Abstract

Background: Prior work has established that fuzzy logic is prevalent in clinical practice guidelines and that Arden Syntax is suitable for representing clinical quality measures (CQMs). Approved since then, Arden Syntax v2.9 (2012) has formal constructs for fuzzy logic even as new formalisms are proposed to represent quality logic. Objectives: Determine the prevalence of fuzzy logic in CQMs and assess the utility of a contemporary version of Arden Syntax for representing them. Methods: Linguistic variables were tabulated in the 329 Assessing Care of the Vulnerable Elderly (ACOVE-3) CQMs, and these logic statements were encoded in Arden Syntax. Results: In a total of 392 CQMs, linguistic variables occurred in 30.6%, and Arden Syntax could be used to represent these formally. Conclusions: Fuzzy logic occurs commonly in CQMs, and Arden Syntax offers particular utility for the representations of these constructs.

Keywords:
Clinical decision support systems; knowledge representation.

Introduction

Fuzzy logic is a multi-valued logic for representing imprecise reasoning. Unlike the typical binary logic employed in knowledge representation (KR) formalisms in clinical medicine, fuzzy logic incorporates degrees of truth or set membership. Clinical quality measures (CQMs) may employ fuzzy logic, using linguistic variables containing modifiers such as “severe” and “partial” without necessarily defining them .

The Arden Syntax standard is a computable formalism for procedural medical knowledge that has been adopted by several vendors. Knowledge is represented in units known as medical logic modules (MLMs). Prior work has established the significant prevalence of fuzzy logic in clinical practice guidelines (100% of a sample had at least 1 linguistic variable) [1] and the utility of the Arden Syntax for representing CQMs, specifically a subset of measures Assessing Care of the Vulnerable Elderly (ACOVE-3) applicable to EHR system and administrative data that were published by RAND in 2007[2]. More recent work has established formal constructs for fuzzy logic representation, including variable declarations and logic statements, in v2.9 of the Arden standard certified in 2012.

Nevertheless, despite this demonstrated prior utility, additional formalisms have been proposed to represent CQMs. The present work was undertaken, in light of recent incorporation of support specifically for fuzzy logic representation in contemporary versions of Arden, to assess the value of these constructs and the consequently improved utility of Arden for representation of CQMs.

Methods

Expanding from the subset of 36 ACOVE-3 CQMs previously used in the assessment of the utility of Arden Syntax as a formalism for CQMs, all 392 ACOVE-3 CQMs were tabulated for the presence of linguistic variables. Logic statements containing these variables then were encoded in Arden Syntax.

Results

The instrument (VES-13) used to determine that an elder is vulnerable, which is a condition of all the ACOVE-3 CQMs, itself contains 3 self-evaluation linguistic variables applied to 6 different criteria. Of the 392 CQMs, 120 (30.6%) contained at least 1 linguistic variable. Four of these contained 2 linguistic variables to yield a total of 124 in ACOVE-3.

Conclusions

A large corpus of CQMs had fewer measures (30.6%) with linguistic variables than a prior corpus of clinical practice guidelines (100%). Nevertheless, fuzzy logic is sufficiently prevalent in CQMs such that, when coupled with prior evidence of its utility for representing CQMs, Arden Syntax--with its new formal constructs for fuzzy logic--offers particular utility for such representation.

Developing a Standards-Based Information Model for Representing Computable Diagnostic Criteria: A Feasibility Study of the NQF Quality Data Model

Guoqian Jiang[a], Harold R. Solbrig[a], Jyotishman Pathak[a], Christopher G. Chute[a]

[a] *Mayo Clinic College of Medicine, Rochester, MN, USA*

Abstract

The lack of a standards-based information model has been recognized as a major barrier for representing computable diagnostic criteria. In this paper we describe our efforts in examining the feasibility of the Quality Data Model (QDM)–developed by the National Quality Forum (NQF)–for representing computable diagnostic criteria. We collected the diagnostic criteria for a number of diseases and disorders (n=12) from textbooks and profiled the data elements of the criteria using the QDM data elements. We identified a number of common patterns informed by the QDM. In conclusion, the common patterns informed by the QDM are useful and feasible in building a standards-based information model for computable diagnostic criteria.

Keywords:

Diagnostic Criteria; Quality Data Model (QDM); ICD-11 Content Model; ISO 11179 Model.

Introduction

For decades clinicians have recognized that their practices greatly benefit from scientifically-based diagnostic criteria, iteratively improved through ongoing research [1]. With recent advances in computerized patient records systems there is an urgent need for producing computable and standards-based diagnostic criteria that could be utilized more effectively in clinical and translational applications, ultimately improving patient care. The lack of a standards-based information model has been recognized as a major barrier for achieving computable diagnostic criteria. The objective of this study is to describe our efforts in developing a standards-based information model for computable diagnostic criteria.

Methods

We established a library of diagnostic criteria for a collection of diseases and disorders. We profiled these diagnostic criteria using QDM elements. National Quality Forum (NQF) developed the Quality Data Model (QDM), which is an information model for representing electronic health record-based quality "eMeasures" [2]. We identified individual criteria from each disease or disorder and profiled them with QDM elements. We analyzed the distribution of QDM elements and identified common patterns for representing the diagnostic criteria. We developed an information model for representing diagnostic criteria by integrating QDM and ICD-11 content models in a Semantic Web-based framework.

Results

We searched electronic medical textbooks from the Mayo Clinic Library website using keywords "Diagnostic Criteria" and selected a collection of diagnostic criteria from 12 diseases or disorders. In total, 139 individual criteria were identified and used as a test set for further analysis. We profiled all 139 criteria using QDM elements in terms of QDM categories, datatypes, and attributes. In total we identified eight QDM datatypes and their attributes from eight distinct QDM categories; of these QDM datatypes, five are most commnly used: "Laboratory Test, Performed;" "Diagnostic Study, Performed;" "Diagnosis, Active;" "Physical Exam, Performed;" and "Symptom, Active."

Discussion

The study is motivated by the requirement of the WHO ICD-11 revision project, in which the creation of diagnostic criteria for the diseases and disorders in ICD-11 has been proposed as a key component for its revision. In this study we used a data-driven approach to evaluate the feasiblity of using QDM to represent diagnostic criteria. We developed a standards-based information model informed by the QDM and ICD-11 content models. We envision that the QDM-based information model and tools for representing quality measures could be used to tackle the challenges in achieving computable diagnostic criteria. This study suggests that the common patterns informed by QDM are useful and feasible in building a standards-based information model for computable diagnostic criteria.

A Standards-based Semantic Metadata Repository to Support EHR-driven Phenotype Authoring and Execution

Guoqian Jiang[a], Harold R. Solbrig[a] , Richard Kiefer[a], Luke V. Rasmussen[b], Huan Mo[c], Peter Speltz[c], William K. Thompson[b], Joshua C. Denny[c], Christopher G. Chute[a], Jyotishman Pathak[a]

[c] Vanderbilt University, Nashville, TN, USA.

Abstract

This study describes our efforts in developing a standards-based semantic metadata repository for supporting electronic health record (EHR)-driven phenotype authoring and execution. Our system comprises three layers: 1) a semantic data element repository layer; 2) a semantic services layer; and 3) a phenotype application layer. In a prototype implementation, we developed the repository and services through integrating the data elements from both Quality Data Model (QDM) and HL7 Fast Healthcare Inteoroperability Resources (FHIR) models. We discuss the modeling challenges and the potential of our system to support EHR phenotype authoring and execution applications.

Keywords:

Metadata Repository; Clinical Phenotyping; Quality Data Model (QDM); HL7 FHIR.

Introduction

The Quality Data Model (QDM) is an information model developed by the National Quality Forum (NQF) and a promising candidate for representing EHR-driven phenotyping algorithms for clinical research [1]. In this study, we extend the Semantic Web-based framework of a previous study that provides a standards-based, semantically annotated, machine-readable rendering of the QDM [2], and develop a semantic metadata repository and associated Web services by integrating HL7 FHIR data element models [3]. Integrating the data elements provides a more comprehensive coverage for clinical phenotype applications.

Methods

Our system is comprised of first a semantic data element repository layer, in which we leverage both W3C standards, such as Resource Description Framework (RDF) and Web Ontology Language (OWL), and the meta-data standard ISO 11179 [4] to describe the QDM reference model, data model elements and logic elements. The second layer is a semantic services layer, while the third layer is a phenotype application layer.

In our previous study [2], we developed a QDM schema in OWL representing the QDM reference model. In this study, we extended the schema with the notions of HL7 FHIR Datatypes and Resources, and is designed as a natural extension of the ISO 11179 standard. We populated the schema with data elements from HL7 FHIR models as QDM schema instances (Table 1), and developed RESTful services on the repository (https://github.com/PheMA/phema-mdr), being utilized by a phenotype authoring tool under active development.

Table 1 – Populated data elements

	QDM	HL7 FHIR	Examples (FHIR)
Category	18	99	Medication
Datatype	76	99	Medication
Attribute	528	1021	Medication Kind
Value Set	-	180	Medication Kind
Logic Element	53	-	-

Conclusion

Our system provides a standards-based semantic infrastructure in enabling data element services to support phenotype authoring and execution. In future work, we plan to develop a standard interface mechanism with Clinical Information Modeling Initiative (CIMI)-compliant clinical models.

Development of an Adolescent Depression Ontology for Analyzing Social Data

Hyesil Jung, RN[a], Hyeoun-Ae Park, PhD, RN, FAAN[a,b], Tae-Min Song, PhD[c], Eunjoo Jeon, MS, RN[a], Ae Ran Kim, MS, RN[a], Joo Yun Lee, MS, RN[a]

[a] College of Nursing, Seoul National University, [b]Research Institute of Nursing Science, Seoul National University, Seoul, Korea, [c]Korea Institute for Health and Social Affairs

Abstract

Depression in adolescence is associated with significant suicidality. Therefore, it is important to detect the risk for depression and provide timely care to adolescents. This study aims to develop an ontology for collecting and analyzing social media data about adolescent depression. This ontology was developed using the 'ontology development 101'. The important terms were extracted from several clinical practice guidelines and postings on Social Network Service. We extracted 777 terms, which were categorized into 'risk factors', 'sign and symptoms', 'screening', 'diagnosis', 'treatment', and 'prevention'. An ontology developed in this study can be used as a framework to understand adolescent depression using unstructured data from social media.

Keywords:

Depression, Adolescent, Ontology, Social media

Introduction

According to OECD Health Data, the suicide rate in South Korea was 29.1 per 100,000 people in 2012, the highest among OECD members states. Moreover, suicide is the leading cause of death among South Korean adolescents. According to a study, approximately 80% of suicides are related to depression. Adolescent depression has the course of chronic relapsing and affects interpersonal realationships and learning ability. Therefore, early detection and intervention are important considerations. Nowadays, big data analytical techniques and extraction methods to derive valuable information at the individual level, are in the spotlight. In Korea, 77.1% of youth own a SNS account[1] and they record their daily activities and openly express their emotions on their social network. Therefore, it is possible for us to use social analytics to monitor activities and sentiments of these adolescents. The aim of this study is to develop an ontology that can be used as a framework for analyzing SNS data to detect danger of adolescent depression and provide timely care.

Methods

An ontology was developed based on 'Ontology development 101'[2]. First, we reviewed exsisting ontologies and then collected important terms in the ontology from several clinical practice guidelines and Twitter postings and enumerated them. Second, we defined the classes and the class hierarchy of the extracted terms. Third, we defined the properties of classes and created instances. Finally, we developed an ontology linking these classes.

Results

We searched on Pubmed and Google Scholar using the keywords 'adolescents'/youth depression ontology'. However, there were no ontologies available. We extracted 777 terms from clinical practice guidelines and Twitter. In this study, six domains(top-classes) and 134 sub-classes were drawn from the enumerated terms. 'Risk Factors' range from individual, family, and social context such as school and community. After 'screening' the 'risk factors' and 'sign & symptoms' of individual, we made a 'diagnosis' of depression. If an adolescent is diagnosed with depression, 'treatment' will be needed. However, if he/she is determined to be a normal or vulnerable individual, 'prevention' services will be followed. Figure 1 illustrates relationships among classes in ontology.

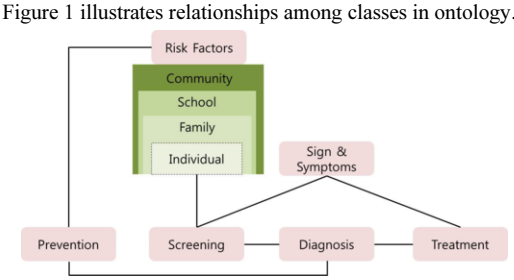

Figure 1. An ontology of adolescent depression

Conclusion

We have developed an adolescent depression ontology based on terms extracted from the clinical practice guidelines and SNS. The ontoloy developed in this study will be used as a framework to monitor youth depression using social media data.

A Framework for Modeling Workflow Execution by an Interdisciplinary Healthcare Team*

Mounira Kezadri-Hamiaz[a], Daniela Rosu[a], Szymon Wilk[b], Craig Kuziemsky[a], Wojtek Michalowski[a], Marc Carrier[c]

[a] *Telfer School of Management, University of Ottawa, Canada*
[b] *Institute of Computing Science, Poznan University of Technology, Poland*
[c] *Ottawa Hospital Research Institute, The Ottawa Hospital, Canada*

Abstract

The use of business workflow models in healthcare is limited because of insufficient capture of complexities associated with behavior of interdisciplinary healthcare teams that execute healthcare workflows. In this paper we present a novel framework that builds on the well-founded business workflow model formalism and related infrastructures and introduces a formal semantic layer that describes selected aspects of team dynamics and supports their real-time operationalization.

Keywords:
Patient Care Team; Workflow; Health Information Systems.

Introduction

Patient management processes are being standardized and formalized as workflows, which in healthcare environment are executed by an interdisciplinary healthcare teams (IHTs). While there has been extensive research on the formalization and execution of business workflows [1], its applicability in the healthcare domain is limited. Limited expressiveness of the business workflow models restricts the ability to represent operations of an IHT, in particular the role of Most Responsible Physician (*MRP)*, team member's role variability and membership dynamics [2]. Role variablity implies that team members may play multiple and different roles when executing workflow tasks, while membership dynamics means that members may join and leave team at any time. Thus, to improve expressiveness of workflow models, a dedicated modeling framework needs to formalize the structure and behavior of an IHT.

Methods

In this poster, we present the *Team and Workflow Management Framework* (TWMF) that extends business workflow models to support the behavior (understood as team formation, management and task-practitioner allocations) of an IHT. The TWMF is designed to be executed in an environment where multiple patients are managed simultaneously by different IHTs and it relies on a set of assumptions that are briefly discussed below. An IHT is formed when a new patient with a certain presentation is admitted and her management (according to a disease-specific workflow) starts. Each IHT includes a MRP who is responsible for patient management and has special duties such as handling exceptional situations. The IHT members are recruited and released dynamically from among available practitioners, as dictated by the execution of the tasks in the workflow. The recruitment and assignment of team members to tasks is done by matching their clinical expertise with the expertise required for completing the tasks. We assume that a practitioner possesses several regularly updated capabilities each with a specific competency level, and that a task execution requires one or more capabilities with associated competency levels. A practitioner can be assigned to a task if she possesses the required capability at a competency level that is at least as good as the competency level identified for the task. TWMF introduces a semantic layer that fomalizes all these aspects through the ontology describing all required concepts, behavioral rules describing team behavior, and an instance base containing all necessary instances of the ontology concepts. The semantic layer is encoded in First-order logic (FOL) [3] formalism.

Results

TWMF is operationalized through a *Team and Workflow Controller* which interfaces with the *Hospital Information System* and the FOL *Reasoner* that operates on the semantic layer and drives workflow execution by an execution engine (such as IBM's Business Process Manager).

Conclusions

We have presented a novel framework for modeling workflow execution by an IHT. It relies on a semantic layer that captures team behavior and team dynamics.

We are testing a framework for different clinical scenarios and we are working on its extension to include durative tasks.

Evaluating a Hierarchical Clinical Event Linkage Model for Clinic-Specific Databases

Justin Liu, BASc[a], Tran Truong, BMath[a]

[a] *Health Informatics Research, University Health Network, Toronto, ON Canada*

Abstract

A relational database model is presented that stores the hierarchical linkages between clinical events with qualifier codes, such that the explicit contextual meaning of an event's attributes is preserved upon retrieval. A retrospective analysis of 302 forms built upon the model showed that 91% of 17,899 data elements requested by clinicians and researchers from 19 clinics were successfully represented, but that 62% were never used more than once. These results reinforce the specificity of clinic-specific databases and the need for unambiguous, explicitly-stored clinical data.

Keywords:

Databases, Factual; Patient-Specific Modeling; Models, Computer; Models, Decision Support; Medical Records.

Introduction

The Explicit Clinical Event Linkage (ExCEL) data model was created to adapt to the granularity and variation of data requirements inherent in different clinical and research settings; this domain-specific data is not typically captured in standard EHR's or contained in the narrative of clinical notes [1,2]. The model is currently implemented in relational databases – such as Oracle, MySQL, and MSSQL – for an array of software (eCancerCare, CKCIS, eColposcopy, UHN OR Notes) to store clinical data for 302 forms for 19 clinics across 5 institutions. The goal of the ExCEL model is to avoid misinterpretations and medico-legal issues that arise from data ambiguity and duplication when retrieving data for clinical documentation, research studies, and decision support.

Methods

The ExCEL model captures 36 types of clinical event entities. Each clinical entity stores atomic, single-valued attributes with distinct clinical meaning (e.g. a procedure entity has a start date attribute); eligible attributes are coded using SNOMED CT. However, a biopsy procedure date can be captured in a clinic note for a past biopsy in the patient's history, for a biopsy performed at the visit, or for a planned biopsy. In order to also store the contextual meaning of the procedure date attribute, hierarchical linkages between clinical events are stored with qualifier codes (SNOMED CT where possible) with explicit meanings. Data fields requested by clinician stakeholders led to very complex hierarchies of events, e.g., "the interventional outcome of a bipolar coagulation performed as an intervention for esophagitis observed in an esophageal exam performed for a gastroscopy as part of an endoscopy operative report". Any data elements that could not be modeled were handled using a less efficient Entity-Attribute-Value design [3]. A retrospective analysis of all data elements was performed to determine the elements that were successfully represented in the ExCEL model, and the non-recurring elements that were used only once.

Results

Table 1 displays the percentages of modeled and non-recurring data elements classified by type of form. Non-modelable elements were specific to granular clinical situations, e.g., "# of children had before removal of testicles" or "# of 8mm suprapubic ports placed in preparation for prostatectomy".

Table 1– Percentages of Non-Recurring and Missing Elements

Type of form	# elements	% modeled	% nonrecur.
All forms	17899	91%	62%
Surg. Reports	5485	76%	83%
Clinic notes	9437	97%	58%
Other forms	2977	98%	23%

Conclusion

The ExCEL model successfully stores data for 91% of 17,899 data elements requested by clinicians, but 62% are never used more than once. The higher percentage of non-recurring data elements in surgical reports and clinic notes is indicative of the large amount of variation between procedures and disease treatment workflows, which demonstrates the specificity of clinic-specific databases and reinforces the difficulty of creating a standardized clinical data model. This specificity must be preserved, however, as extending the meaning of data beyond what its data model is designed to describe can involve making incorrect assumptions with medico-legal implications when interpreting the data upon retrieval.

Abstract

The development of new methods, devices and apps for self-monitoring have enabled the extension of the application of these approaches for consumer health and research purposes. The increase in the number and variety of devices has generated a complex scenario where reporting guidelines and data exchange formats will be needed to ensure the quality of the information and the reproducibility of results of the experiments. Based on the Minimal Information for Self Monitoring Experiments (MISME) reporting guideline we have developed an XML format (MISME-ML) to facilitate data exchange for self monitoring experiments. We have also developed a sample instance to illustrate the concept and a Java MISME-ML validation tool. The implementation and adoption of these tools should contribute to the consolidation of a set of methods that ensure the reproducibility of self monitoring experiments for research purposes.

Keywords:

Self-monitoring; Data Exchange; Standards; Information Sharing.

Introduction

In recent years we have witnessed an increase in the number of new devices and apps developed for health purposes and self-monitoring. These systems are also being used for biomedical research purposes. Despite of the increase in their use, there is still a great disparity in both the data formats, data analysis and data management approaches as well as on the metadata required for their interpretation. Based on previous successful experiences in other disciplines, we have recently developed a minimal information reporting guideline for self monitoring experiments (MISME) [1], this guideline defined the minimal metadata required for the interpretation of these experiments.

Once a minimal reporting guideline has been proposed, the next step is the development of information processing tools based on those reporting guidelines. Facilitating data exchange in a standardised format represents a crucial step in the development of minimal reporting guidelines. For this purpose, in other disciplines (such as bioinformatics) extended markup languages (XML) have been developed.

In this work we present an implementation of an XML-based data exchange format for self monitoring experiments (MISME-ML) based on MISME as well as a MISME-ML validation tool.

Methods

For the development of the data exchange format we have chosen an extensible mark-up language which captures the information included in the MISME reporting guideline. To facilitate the design and creation of this XML format, we transformed the concepts covered in the MISME reporting guideline into an entity-relationship model. An XML format validation tool was also developed using JAVA.

Results

We have modeled and developed an XML format (MISME-ML) to facilitate the exchange of self monitoring data according to our previously developed minimal reporting guideline MISME. Together with this XML format we have developed a MISME-ML validator tool to assess the quality of the MISME-ML files, checking the different elements that are part of MISME and the nature of the relationships among them, ensuring the existence of the correct relationships among the different elements and avoiding having unrelated data.

Conclusions

With the expansion of self monitoring approaches for research purposes and health applications, there is an increasing need of using standards and methods to ensure the reproducibility and sharability of the results from these experiments.

The development of a data exchange format and the companion XML validation tool come to provide and extend the functionalities related with the minimal information reporting guideline aiming to facilitate the process of data exchange and the reproducibility of the experiments.

Acknowledgments

This work has been supported by an ECR grant of the University of Melbourne.

DServO: A Peer-to-Peer-based Approach to Biomedical Ontology Repositories

Zakaria Mambone[a], Mahamadi Savadogo[a], Borlli Michel Jonas Some[a], Gayo Diallo[b]

[a] *Polytechnic University of Bobo-Dioulasso, Computer Sciences Institute, Burkina Faso*
[b] *University of Bordeaux, INSERM U897, F-33000, Bordeaux, France*

Abstract

We present in this poster an extension of the ServO ontology server system, which adopts a decentralized Peer-To-Peer approach for managing multiple heterogeneous knowledge organization systems. It relies on the use of the JXTA protocol coupled with information retrieval techniques to provide a decentralized infrastructure for managing multiples instances of Ontology Repositories.

Keywords:
Ontology Repository, Biomedical Ontologies, Peer-To-Peer.

Introduction

Presently, new Knowledge Organization Systems (KOS) are proliferating rapidly, ranging from terminologies and structured vocabuaries to formal ontologies with well-defined semantics. As a consequence, there is a need of systems and tools for managing these KOS's and retrieving them in an efficient way in order to be reusable in knowledge-based applications. Several systems have been proposed to address this issue. BioPortal [1] is presently the most popular of these within the biomedical domain. Most of the systems follow a client-server model. This paradigm results in a number of limitations. First, it is not fault tolerant, since a server failure results in data unavailability. Second, when a user publishes an ontology onto a server, they lose the ability to alter it.

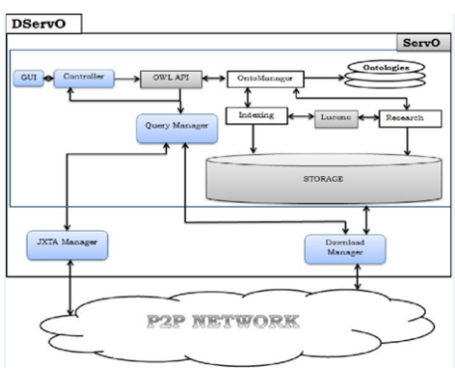

Figure 1 – Architechture of a DServO Peer

In this poster, we propose DServO, an extension of the ServO ontology server [2], which offers a decentralized approach – based on a Peer-To-Peer (P2P) paradigm – for managing multiple ontology servers and making them interoperable.

Methods

We have extended ServO by adding a P2P layer. To do so, we relied on the JXTA technology[1] to create a P2P network of mutiple extended ServO (DServO) instances. Each instance of DServo is constitued by the following components (Figure 1): i) A graphical user interface (GUI), which allows sending queries and retrieving responses; ii) a controller, which takes charge of dispatching user queries to the query manager, and offers services for managing ontologies; iii) a query manager, which mediates between the GUI and controller, and the network layer (JXTA manager); iv) a JXTA manager, which takes charge of all connection management and of discovering peers within the P2P network; and v). a retrieval module which takes charge of retrieving ontologies and ontological entities from the P2P network.

Results

We have implemented DServO in Java using the OWL API as an ontology manager, and the Apache Lucene as an information retrieval library. The system is able to handle efficiently very large OWL and RDF KOS's with hundreds of thousands of entities – such as SNOMED CT and the NCI Thesaurus – in a timely manner.

Conclusion

DServO has been succefully evaluated by instatiating 4 nodes of ontology servers and handling various – sometimes duplicated – biomedical KOS's.

OntoMama: An Ontology Applied to Breast Cancer

M.T.D. Melo[a], V.H.L. Gonçalves[a], H.D.R Costa[a], D.S Braga[a], L.B Gomide[a], C.S Alves[a], L.M. Brasil[a]

[a] *University of Brasília (UnB) at Gama (FGA), Brazil*

Abstract

This article describes the process of building an ontology to assist medical students and professionals specialized in Oncology. The ontology allows the user to obtain knowledge more quickly and thus assist professionals in their decision-making.

Keywords:
Breast Cancer, Ontology, OntoMama.

Introduction

Technological advances are having a strong impact in the health sector. Information technology, for example, which seeks improvements in the processing and dissemination of data, assist health professionals in their work [1].

The human body consists of several structures organized hierarchically. For the process of learning the human body, including the study of dysfunctions, it is necessary to organize these structures according to their concept, relationships and functions, in order to facilitate identi-fication to these elements [2].

An example of pathology that affects the functioning of the organism is breast cancer. This type of cancer develops in the mammary gland as a result of genetic changes in some set of breast cells [2]. This article presents the development of OntoMama, an ontology to assist professionals and students specialized in Oncology. It consists of a query web service that provides conceptual information, images, videos and prototypes developed in an environment of three-dimensional (3D) modeling.

Materials and Methods

The domain and scope established for the development of the ontology are linked to breast cancer. The methodology adopted was the METHONTOLOGY and the construction tool chosen was the editor for ontologies and knowledge bases Protégé.

Results

Figure 1 shows the topics that compose the ontological model. This model is partially implemented because there is a need to standardize the structures with bibliographic material.

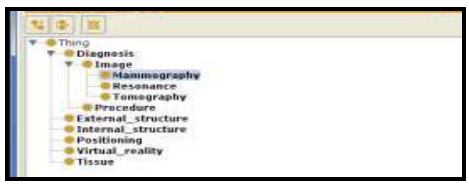

Figure 1 – OntoMama Model.

Conclusion

This article introduced the development of an ontology for to the study of breast cancer. The next step is to complete the ontology with textual content, 3D models, images, and videos for each element. The implementation phase will be finalized with an Intelligent Tutor System (ITS) based on the ontological model developed [3].

National Healthcare Policies in Chile: An Ontological Meta-Analysis

Alicia Núñez Mondaca[a], Arkalgud Ramaprasad[b], Thant Syn[c]

[a]Universidad de Chile, [b]University of Illinois at Chicago, [c]Texas A&M International University

Abstract

We present an ontological meta-analysis of the national healthcare policies in Chile. Using a logically constructed ontology based on the common body of knowledge as a lens, we map the 39 key policies. The ontological map provides a synoptic, systematic, and systemic view of the policies, and highlight their emphases and biases.

Keywords:

Health Care Economics and Organizations [N03]; Health Care Quality, Access, and Evaluation [N05], Health Services Administration [N04], Health Policy [I01.655.500.608.400]

Introduction

The evolution of the laws indicates that Chile is moving towards universal access to affordable and quality healthcare. However, it is necessary at this point to have a global view of the policies that have been implemented in the country, assess them, and then decide the future direction of the healthcare system. Ontological meta-analysis will help us to efficiently formalize, standardize, and manage the information regarding the policies that have shaped today´s healthcare system, and design future policies to fill the gaps.

Results

The ontological map of monads – individual categories in the ontology – is shown in Figure 1. The number in parentheses adjacent to the category indicates its frequency of occurrence in the 39 policies. The bar below the category is a visual indicator of the same scaled to the maximum number of occurrences of any one category (National – 39). On the one hand, Financial and Regulatory Policies and National focus are highly emphasized; Technology policies and Satisfaction and Timeliness outcomes are hardly emphasized. Yet, almost all elements in the ontology find expression in at least one policy – an indicator of their extensive coverage.

Discussion and Conclusion

A majority of the policies are financial, regulatory, and administrative; just a few of them target the insurance structure. The country needs policies intended to create a system for financing health services that at the same time is adequately managed. A system that guarantees outcomes such as quality and safety, which have been addressed in past health policies, should always be a priority. Policies should also provide access to essential medicine and technologies

Modelling the Medication Management System for Resource Limited Settings: A Formal Representation of the Prescribing and Dispensing Phases

William Ogallo, Andrew S. Kanter

Department of Biomedical Informatics, Columbia University, New York, USA

Abstract

We propose a conceptual data model for relational databases targeting the prescribing and dispensing phases of the medication management system. The model was developed using recommendations from existing standards and guidelines, with necessary modifications made to suit adoption in resource-limited settings. We present the model as an entity-relationship diagram with 10 entities, 12 relationships and 48 attributes. It is our hope that this work will help mitigate barriers in the implementation of electronic prescribing and dispensing standards in the developing world.

Keywords:

Medication Systems, Hospital; Developing Countries.

Introduction

The medication management system refers to the continuum of prescription writing, prescription transmission, medication dispensing, medication administration and medication therapy monitoring. While standards and recommendations for modelling the electronic information within this domain are available, they primarily exist in the form of textual narratives. The goal of this study was to create and visualize a conceptual model for the prescribing and dispensing phases of the medication management system primarily targeting implementation in resource-limited settings.

Methods

We scrutinized existing literature evidence to understand the workflows, processes, activities, tasks, actors and data elements associated with the two phases. We synthesized the information to understand what data needed to be stored and how these should be structured. We then developed a high-level semantic description of the data and their associated constraints, using the Entity-Relationship model.

Results

The model has a total of 10 principal entities, 12 one-to-many relationships and 48 attributes (Figure 1). The key actors are the *Patient*, *Prescriber* and *Dispensing Staff* who must be uniquely identified. The *Prescription* entity refers to the order for supply of a medication to a particular patient. Attributes of the *Prescribed Drug Information* entity are the action information about the prescribed drug. The *Dispensing Record* entity is the record in response to a prescription showing that a particular medication was supplied to a particular patient and instructions of administration provided. The *Dispensed Medication Information* entity contains attributes that describe the dispensed medication and the *Refill Record* entity is the record tracking the refill history of every dispensed medication.

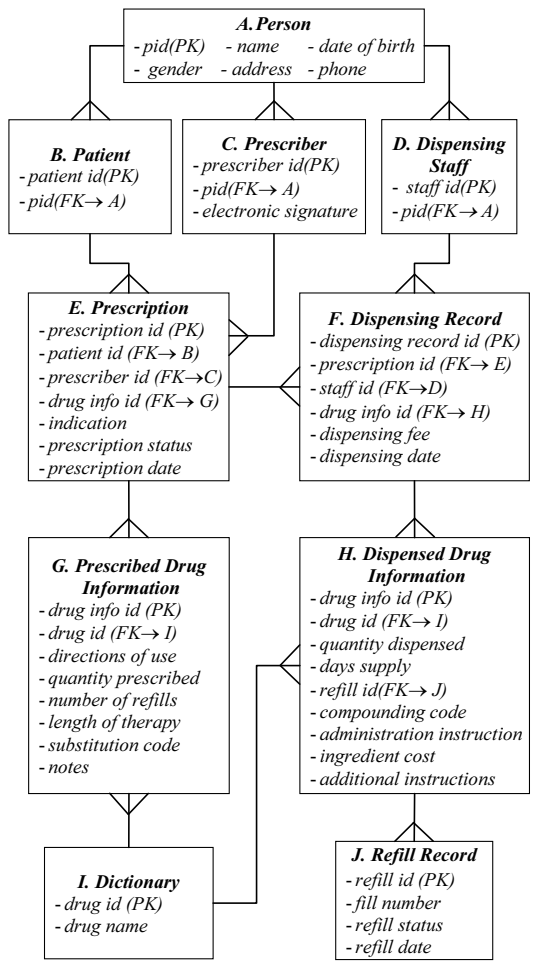

Figure 1 - Entity-Relationship Diagram for the Prescribing and Dispensing Phases

Conclusions

We propose a conceptual model for electronic prescribing and dispensing databases. The model is consistent with current standards and is applicable in resource-limited settings.

Real-time Data Fusion Platforms: The Need of Multi-dimensional Data-driven Research in Biomedical Informatics

Satyajeet Raje[a], Bobbie Kite[b], Jay Ramanathan[a], Philip Payne[b]

[a] *Department of Computer Science and Engineering, The Ohio State University, Columbus, OH, USA*
[b] *Department of Biomedical Informatics, The Ohio State University, Columbus, OH, USA*

Abstract

Systems designed to expedite data preprocessing tasks such as data discovery, interpretation, and integration that are required before data analysis drastically impact the pace of biomedical informatics research. Current commercial interactive and real-time data integration tools are designed for large-scale business analytics requirements. In this paper we identify the need for end-to-end data fusion platforms from the researcher's perspective, supporting ad-hoc data interpretation and integration.

Keywords:
Research informatics; knowledge bases; data curation.

Introduction

Data-driven research and analytics is at the core of clinical and translational informatics [1]. Data analysis involves several preprocessing activities such as data exploration, collection, cleaning, curation, interpretation, etc. These activities are a necessary prerequisite to perform analyses and answer research questions, and these activities are time-consuming in current research evnviornments. They can be broadly classified into the steps of data discovery, interpretation, and integration. We identify the need for a data fusion platform that will aid researchers in this time-consuming process.

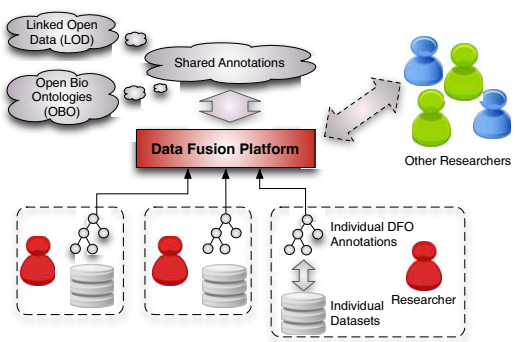

Figure 1– Role of Data Fusion Platforms in research

We define a **data fusion platform** as a system that provides automated, end-to-end, real-time and ad-hoc functionality across the data preprocessing tasks of data discovery, interpretation and integration. As shown in Figure 1, such a platform will serve as a middle-layer between researchers and crowd-sourced data collections promoting faster discovery and interpretation of datasets. It would allow researchers to publish their datasets by leveraging reusable annotations to standard reference ontologies and vocabularies.

Methods

To determine the plausibility of this notion, we conducted an informal interview with researchers, statisticians, and business analysts. To further understand the exact requirements of the researchers and assess the capabilities of the current set of tools to satisfy them, we conducted semi-structured interviews containing 8 questions with 4 biomedical researchers with varying levels of experience working, primarily, in different areas of research. In addition we also interviewed 2 business data analysts and 2 biostatisticians.

Results

The interviews revealed major differences in the process and philosophy of the individual researchers and the large-scale business analytics. About two-thirds of data driven research in biomedical informatics relies on tabular data. Currently, researchers have limited access to automated tools to help in the data preprocessing and usually perform all tasks manually.

Discussion

Informal interviews of researchers, statisticians, and business analysts confirmed that interactive data fusion platforms could serve to bolster the efficiency of multi-dimensional research. Even though existing tools and methods perform individual data preprocessing tasks well, none of the approaches are able to provide an end-to-end, interactive data fusion platform capable of performing in real-time. We argue that a data fusion platform with such capabilities is crucial for the effective research in the modern data environment.

The next step is to formalize and conduct interviews with a larger, more diverse set. The primary focus of ongoing research is to formally articulate the specifics of such systems and the frameworks that would be needed to design and implement them.

Towards a Formal Representation of Processes and Objects Regarding the Delivery of Telehealth Services: The Telehealth Ontology (TEON)

Filipe Santana[a], Stefan Schulz[b], Amadeu Campos[c], Magdala A. Novaes[c,d]

[a] *Centro de Informática (CIn), Universidade Federal de Pernambuco (UFPE), Recife, Brazil*
[b] *Institut für Medizinische Informatik, Statistik und Dokumentation (IMI), Medizinische Universität Graz, Austria*
[c] *Núcleo de Telessaúde (NUTES), Hospital das Clínicas, Universidade Federal de Pernambuco (UFPE), Recife, Brazil*
[d] *Departamento de Medicina Clínica, Centro de Ciências da Saúda (CCS), Universidade Federal de Pernambuco (UFPE), Recife, Brazil*

Abstract

This study introduces ontological aspects concerning the Telehealth Ontology (TEON), an ontology that represents formal-ontological content concerning the delivery of telehealth services. TEON formally represents the main services, actors and other entity types relevant to telehealth service delivery. TEON uses the upper level ontology BioTopLite2 and reuses content from the Ontology for Biomedical Investigations (OBI). The services embedded in telehealth services are considered as essential as the common services provided by the health-related practices. We envision TEON as a service to support the development of telehealth systems. TEON might also enable the integration of heterogeneous telehealth systems, and provide a base to automatize the processing of telehealth-related content.

Keywords:

Telehealth; Biological Ontology; Health Services.

Introduction

The lack of communication between telehealth systems creates (mostly) repetitive data, without any standardisation of the key concept meanings. We therefore recommend the use of ontologies and/or terminologies as a way to enrich the descriptions and content of telehealth-related systems and applications with domain-specific, controlled terms. According to this requirement, the aim of this study is to introduce ontological aspects concerning the Telehealth Ontology (TEON).

Methods

TEON was created using Description Logics (DL) [1], and implemented using the Web Ontology Language v2 (OWL2), built and edited via Protégé v5. TEON expands the upper domain ontology BioTopLite2 (BTL2) [2] and reuses content from the Ontology of Biomedical Investigations (OBI) [3], e.g., the class service that has TelehealthService as a subclass. TEON is available at http://www.nutes.ufpe.br/teon.

Results

TEON formulates classes and axioms to represent the delivery of telehealth services. It includes the description of actors, synchronicity profiles, health teams, and specific processes. Actor is a term related to the bearer of roles during the delivery of services. From telehealth services, there are three main roles: **requestor** (*RequestorRole*); **teleconsultant** (*TeleconsultantRole*); and **manager** (*ManagerRole*).

To express the synchronous profile of services, we took the notion of *PointInTime* and *TimeInterval* from BTL2. When processes are synchronous, their time interval and interval boundaries coincide. Otherwise they are asynchronous.

The notion of service, taken from OBI, describes them as "*planned processes in which two different entities are bearers of consumer and provider roles*" [3]. Telehealth services are delivered for different healthcare specialties such as telecardiology, teledermatology and telepsychiatry. These services are constrained by how they are delivered, e.g., via teleconsultation, second opinion, telediagnosis, among others.

Conclusion

In the current study, we described the formal description of the telehealth services domain in the Telehealth Ontology (TEON). Services that instantiate TelehealthService can be considered to have similar characteristics as common health care services. In addition, the roles played by the actors, the temporal dimensions (synchronicity and asynchronicity), are represented. As an ontology, we envision TEON's use as the formal background to guide the development of telehealth applications and systems. Ontology use in the telehealth domain might overcome the lack of consensus surrounding the terminology and subtleties about what is a service and what is telehealth practice.

Characterizing Health Information for Different Target Audiences

Yueping Sun[a], Zhen Hou[a], Li Hou[a], Jiao Li[a]

[a] *Institute of Medical Information & Library, Chinese Academy of Medical Sciences, Beijing, China*

Abstract

Different groups of audiences in health care: health professionals and health consumers, each have different information needs. Health monographs targeting different audiences are created by leveraging readers' background knowledge. The NCI's Physician Data Query (PDQ®) Cancer Information Summaries provide parallel cancer information and education resources with different target audiences. In this paper, we used targeted audience-specific cancer information PDQs to measure characteristic differences on the element level between audiences. In addition, we compared vocabulary coverage. Results show a significant difference between the professional and patient version of cancer monographs in both content organization and vocabulary. This study provides a new view to assess targeted audience-specific health information, and helps editors to improve the quality and readability of health information.

Keywords:

Target Audience; Element Level; Health Information; Readability.

Introduction

The National Cancer Institute's (NCI) Physician Data Query (PDQ®) Cancer Information Summaries are widely recognized as an important cancer information and education resource, with multiple target audiences [1]. Although general guidelines for the PDQ editors have been provided, no other measurable quality evaluations are available. Existing studies show that it is critical to precisely define measurable data attributes to value the quality of health data. In this paper, we aim to quantitatively compare the contents targeting professionals and patients at both element and vocabulary levels.

Materials and Methods

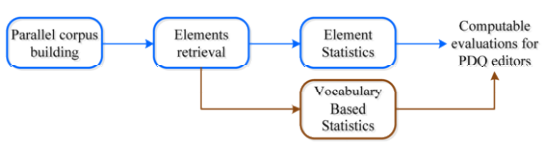

Figure 1– Steps of the characterizing method

The study method consists of 4 steps: 1) building a parallel PDQ corpus that includes both summaries targeting the health professionals and summaries targeting patients; 2) retrieval of elements; 3) statistical comparison of the elements, which returns computable evaluations for PDQ editors; 4) open-access and collaborative (OAC) consumer health vocabulary (CHV) based statistics.

Results

For the element level statistical analysis, we grouped the elements to 4 classes: 1) elements unique in the professional version (Unique in Pro); 2) elements which are remarkably more in the professional version (More in Pro); 3) elements which have similar distributions (Similar in Pro and Pat); 4) elements which are remarkably more in the patient version.

Table 1– Element Classification Results According to Statistics

Classes	Elements
Unique in Pro	LOERef; Refidx; Citation
More in Pro	Table; SummaryRef; Title; Para
Similar in Pro and Pat	ListItem; ItemizedList; SummarySection; ExternalRef; TermRef.
More in Pat	KeyPoint; MediaLink; GrossTermRef

Our results are consistent with the regulations given to PDQ editors. No citations have been found in the patient versions while more illustrations, represented by elements in "More in Pat" have been found. Besides, it is shown that the patient version has no level of evidence information (LOERef). Also we have obtained element distributions for both versions to statistically measure new batches.

The frequencies of an OAC CHV term in the two versions were compared. Considering that the two versions have different sizes, we assign the frequency of a term as 1 when the term appears more than one time in the summary. The overall frequency in the patient version is 260292, while the one in the professional version is 423739. It is shown that the patient targeted summaries cover far fewer OAC CHV terms than the professional ones.

Discussion and Conclusion

We introduced a new perspective of evaluating health information targeting professional and patients from the view of content organization and vocabulary usage. Our study provides quantitative guideline for monograph editors or health information authors to improve composition readability. In future work, context comparisons via Natural Language Processing (NLP) techniques will be explored.

A Pilot Ontology for Healthcare Quality Indicators

Pam White[a] and Abdul Roudsari[b]

[a] *School of Informatics, City University London, United Kingdom*
[b] *Department of Health Information Science, University of Victoria, British Columbia, Canada*

Abstract

Computerisation of quality indicators for the English National Health Service currently relies primarily on queries and clinical coding, with little use of ontologies. We created a searchable ontology for a diverse set of healthcare quality indicators. We investigated attributes and relationships in a set of 222 quality indicators, categorised by clinical pathway, inclusion and exclusion criteria and US Institute of Medicine purpose. Our pilot ontology could reduce duplication of effort in healthcare quality monitoring.

Keywords:

Ontologies; Quality Indicators, Healthcare

Introduction

Quality indicators are useful tools for monitoring healthcare outcomes. When quality indicators are issued by more than one governing body, they may overlap in content. Ontologies can facilitate automated quality monitoring by categorising and establishing relationships between concepts. In England's National Health Service (NHS), quality indicators are frequently measured electronically by using separate queries and data extraction for each quality indicator. An ontology for quality indicators issued from different sources can reduce effort needed to find data for quality indicators by linking common criteria in the indicators.

Method

We developed a pilot ontology that specifies inclusion and exclusion criteria, along with relationships between quality indicators. We categorised a large set of quality indicators [1] by clinical pathway, dimension, and US Institute of Medicine [2] purpose. The Clinical Pathway and Dimension categories were based on a 2008 strategic report for the NHS [3]. We used Statement and Definition metadata from the NHS [4] to specify layers of inclusion and exclusion criteria, creating chunks of indicator components. We then identified broader, narrower, and same level relationships between components of different indicators. We explain further detail about conceptualisation of the ontology in a separate article [5].

Results

Classes and Subclasses

Figure 1 shows the main classes and one of their subclasses.

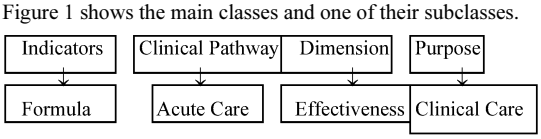

Figure 1. Examples of Classes and Subclasses

Properties

39 properties were assigned to the classes and/or subclasses. The Indicators class has 29 properties, with a maximum depth of seven layers of Inclusion/Exclusion Criteria (an exmaple of properties, due to different characteristics and names of the criteria).

Discussion

Our ontology was intended to make components of the indicators searchable, with a potential to reduce duplication of effort in finding data for common components of quality indicators from different sources. A use case example would be a clinical auditor seeking blood pressure measurement records within the past 9 months, for patients with hypertension. The auditor could search the ontology, using the keyword 'hypertension' to find related indicators. For example, they would find an indicator requesting records of lifestyle advice given to patients with hypertension. They would only need to search for records of patients with hypertension once to compile data for different indicators.

Conclusion

Our ontology offers the ability to search components of quality indicators from different sources, with a view to reducing duplication of effort in gathering data for indicators with common criteria. Although the ontology is useful in its present form, it would benefit from revision to improve its structure and to reduce the number of properties.

Fuzzy-Arden-Syntax-based, Vendor-agnostic, Scalable Clinical Decision Support and Monitoring Platform

Klaus-Peter Adlassnig[a,b,*], Karsten Fehre[b], Andrea Rappelsberger[a]

[a] *Section for Medical Expert and Knowledge-Based Systems, CeMSIIS, Medical University of Vienna, Vienna, Austria*
[b] *Medexter Healthcare GmbH, Vienna, Austria*

Abstract

This study's objective is to develop and use a scalable genuine technology platform for clinical decision support based on Arden Syntax, which was extended by fuzzy set theory and fuzzy logic. Arden Syntax is a widely recognized formal language for representing clinical and scientific knowledge in an executable format, and is maintained by Health Level Seven (HL7) International and approved by the American National Standards Institute (ANSI). Fuzzy set theory and logic permit the representation of knowledge and automated reasoning under linguistic and propositional uncertainty. These forms of uncertainty are a common feature of patients' medical data, the body of medical knowledge, and deductive clinical reasoning.

Keywords:
Arden Syntax;fuzzy methodologies; clinical knowledge representation;health IT integration and application.

Introduction

Arden Syntax is a medical knowledge representation and processing scheme for clinical decision support (CDS) systems. It originated in 1989 at a gathering of several medical informatics specialists from the USA, the Netherlands, and Sweden, at the Arden Homestead Retreat in Orange County, NY. The latest HL7- and ANSI-certified release is Arden Syntax version 2.10, which was approved in October 2014 [1]. This version consists of an augmented Arden Syntax, completely extended by fuzzy methodologies and ArdenML, an XML representation of the Arden Syntax code.

Methods

Medical logic modules (MLMs) are the basic representation and processing units in Arden Syntax. To execute MLMs written in Arden Syntax, one needs to write an interpreter or compiler for Arden Syntax, and an execution environment to process the MLMs. In addition, an authoring tool containing an editor for writing MLMs—which includes an execution engine for testing them before they become enacted—needs to be provided with such a suite of Arden Syntax software.

Following current software architectures and providing the Arden Syntax execution rule engine within a service-oriented architecture make it possible to offer CDS systems for a variety of tasks. In addition, clinical linguistic uncertainty can now be modeled using fuzzy sets; and propositional uncertainty can be expressed by rule-associated truth values. The computed results are then propagated and aggregated by fuzzy logic.

Results

We developed an authoring and testing environment, including an Arden Syntax version 2.10 compiler to write MLMs and compile and test the environment immediately. Based on an Arden Syntax rule engine, which executes the compiled MLMs, an Arden Syntax server is built around this engine to enable service-oriented access to and from client applications. To connect the server with host systems and data sources, three basic forms of technical integration were established:

1. *Web services for calling and data*: MLM and event calls are realized by SOAP or RESTful web services, with the service call also transferring the necessary data required for MLM processing.
2. *Web services for calling and server/database connector*: The second form of interconnecting is to call MLMs and events through SOAP or RESTful web services, but to access patient data directly from data sources through a so-called server/database connector (being an add-on to the Arden Syntax server).
3. *Data warehouse + rule engine = autonomous clinical decision support system*: Here the Arden Syntax server—including its rule engine and database connector—accesses a project-specific data warehouse (which can be quite general and extensive). This data warehouse receives "raw" patient data through communication servers or import routines from any external data source (in, e.g., HL7/XML/SQL format).

Conclusion

This technical solution was shown to be deployable in connection with hospital and intensive care information systems and with smart phone apps and research databases. The solution proved useful in a number of clinical fields.

Online Training Assessment For Primary Care Professionals Of The City Of São Paulo

Debora Cristina Alavarce[a], Heloisa Helena Ciqueto Peres[b]

[a] *School of Nursing, USP, São Paulo, Brazil*
[b] *Dep. ENO, School of Nursing, USP, São Paulo, Brazil*

Abstract

Students who participate in courses and training offered in distance mode receive positive results in learning evaluations. Most studies show improvement in knowledge in pre- and post- course comparisons; however, there are still few evaluations of long-term knowledge retention. This study compares the learning scores of online training for health professionals in three different times: before training, immediately after, and 180 days later. This technological production research includes quantitative, descriptive and multivariate correlational, longitudinal, and panel types. The results show that online training has a positive impact on learning and knowledge retention. Whereas learning can be related to the impact of training, i.e., with the transfer of what was gathered for professional practice, learning retention of online training applied to health professionals represents an important step and assists in identifying the best strategies so expected results are achieved.

Keywords:

Service training;Distance education; evaluation;Evaluation of learning.

Introduction

Online training includes a set of technologies and media, organized based on theoretical assumptions of education and communication. The present study adopted the theory of meaningful learning in order to support an analysis of the learning process and knowledge retention of online training for health professionals.

The learning evaluation is an important tool for estimating the adequacy of procedures and educational strategies used in training and to make it possible to assess whether the individual in fact learned what was taught. The evaluation serves also as a tool to demonstrate the effectiveness of the training and subsidizes the perfection of training itself, as well as needs assessment, evaluation of results, assisting managers and organisers of training to control the quality of their actions [1].

Materials and Methods

This study deals with the technological production linked to research foundations and management practice in nursing and health of the graduate program in nursing management (PPGEn) of the nursing school at the University of São Paulo (EEUSP). This group includes studies and research of information technology in work processes in nursing (GEPETE/EEUSP).

The technological product developed in this study was an online training on the topic identification of dementia in the elderly. The training was organized into 4 units with a schedule provided of 20 hours, the LMS used was Moodle ®. The units were developed using different learning digital objects. Each module contained a different activity, such as discussion forums, case study and practical cognitive assessment activity.

The study site was a specialized outpatient health services for the elderly located in a region of São Paulo / BR and students were graduates health profissinais who worked in the basic health units of the region.

Results

The learning evaluation applied in three different time frames was characterized as shown in Table 1:

- The assessment of learning online pre-training presented an average mark of 6.24 + 1.25. (Pre)
- The immediate evaluation was significantly higher with an average of 7.66 + 1.21 with an estimated gain of 1.41 points on the first note. (Pós1)
- Late Review, which kept an average of 7.24 + 0.84, and estimated gain of this compared to pre-training assessment online was 0.96 points. (Pós2)

Table 1 - Distribution of Average and Standard Deviation and Notes Obtained by Pupils

Type	N	Min	Max	Average	SD
Pre	40	3,66	8,68	6,24	1,25
Post 1	39	5,33	10	7,66	1,21
Pos 2	37	5,84	10	7,24	0,84

The survey results demonstrate that there has been a significant gain in immediate and long-term review when compared with the pre training notes. The Group proved to be heterogeneous in both the assessment moments that can be perceived by maintaining the standard deviation in 1.2.

Allergy Risk Finder: Hypothesis Generation System for Allergy Risks via Web Service

Eiji ARAMAKI, Ph.D.[a], Shuko SHIKATA[a], Eriko WATABE[b], Mai MIYABE, Ph.D.[a], Yasuyuki USUDA[c], Satsuki AYAYA[d], Shinichiro KUMAGAYA, Ph.D. M.D.[d]

[c] *The Graduate School of Human Environment of Sciences, Kyoto University*
[d] *Research Center for Advanced Science and Technology, The University of Tokyo*

Abstract

This study's aim was to build a web service that automatically collects and tests hypotheses for possible allergy risks. We crowdsourced for unknown allergy risks, and obtained odds ratios. By using the collected hypotheses, we built a web service that estimates allergy risks from a questionnaire (consisting of 10 questions that we gathered from the crowdsourcing task), and at the end, we asked the users their new hypotheses on possible allergy risks. The web service also asked the users to send their original hypotheses to contribute to find the cause of allergy. In the near future, clinical trials to validate the hypotheses found in this study are desired.

Keywords:

Crowdsourcing;Web service;Hypothesis generation;Allergy risk; e-health.

Introduction

This study generates clinical hypotheses by asking the public through our original website, the *Allergy Risk Finder*. Hypothesis generation is one of the most essential tasks for clinical research, and several studies have attempted to crowdsource such tasks [1-4]. This study used possible risks brought up by crowdsourcing tasks, and incorporated the risks in the seed questions All processes in this research were via the *Allergy Risk Finder*.

Materials and Methods

We set the known risks using review paper survey and the governmental guideline for allergy [5]. We extracted 29 hypotheses, and 8 of them were used for the system as the seed questions. The other 21 were used for evaluation. Firstly, the users filled in the questionnaire items (hereafter, questions), and the questions changed as the number of users increased. The questionnaire consisted of three types of questions: (1) Profile questions obtained the profile of the user; having allergy or not, his/her gender and age, (2) Risk questions (contained seed and newly proposed questions by users in (3)); asked the user's environmental situation by randomly selecting the allergy hypotheses from the risk pools, and (3) Original risk-proposing questions survey to propose novel allergy risks (1 to 5 answers required); used as the questions for the next and further round.

We repeated this procedure five times. Potentially promising top 100 hypotheses with high odds ratios were kept in the allergy risk pool, and the other hypotheses with lower potential were discarded.

Results

Since this service has launched, the *Allergy Risk Finder* has already found more than 152 new hypotheses of allergy risks. We evaluated the performance of the already-known risks with the following 2 aspects: (1) the propotions of already-known risks found within the users' answers, and (2) we used 21 already-known risks to evaluate the propotions of hypotheses produced by users with high odds ratios (over 1.0 in lower bound of 95% confident interval). The 152 newly proposed risks included all 21 already-known risks, which suggested the broad coverage of the *Allergy Risk Finder*. Among all newly proposed hypotheses of allergy risks, 43 hypotheses showed odds ratios of over 1.0. It was notable that these included 13 already-known risks, indicating the validness of this process.

Conclusion

The *Allergy Risk Finder* could show the whole allergy research process from hypothesis generation to questionnaire-based validation. Clinical trials to validate the hypotheses found in this study are desired.

Toward a Global eHealth Observatory for Nursing

Claudia C. Bartz[a], Nicholas R. Hardiker[b], Amy Coenen[c]

[a] *International Council of Nurses, Geneva, Switzerland*
[b] *School of Nursing, Midwifery, Social Work & Social Sciences, University of Salford, UK*
[c] *College of Nursing, University of Wisconsin-Milwaukee, Milwaukee, WI, USA*

Abstract

This poster summarizes a review of existing health observatories and proposes a new entity for nursing. A nursing eHealth observatory would be an authoritative and respected source of eHealth information that would support nursing decision-making and policy development and add to the body of knowledge about professional nursing and client care outcomes.

Keywords:

Observatory; eHealth; Nursing.

Introduction

eHealth is the use of information and communication technologies (ICT) for health. The aim of knowing who, what, when, where, why and how of "eHealth" has resulted in the emergence of eHealth observatories. Professional observatories are essentially institutions or entities that monitor and evaluate a selected topic over time. The health community is trying to more deliberately describe and advance its eHealth universe.

A global eHealth observatory for nursing is needed. The purpose of this poster is to propose an international eHealth observatory for nursing that would consider nursing eHealth roles, projects and research that would contribute to knowledge about professional nursing and client care outcomes in eHealth environments.

Methods

The work was carried out under the auspices of the International Council of Nurses (ICN) eHealth Programme.

First, using descriptive methods, published and web-sourced materials of health-related observatories were examined for characteristics applicable to a nursing eHealth observatory.

Second, a multidisciplinary team of eHealth and policy experts was tasked by ICN to envision an eHealth observatory for nursing and provide input into the planning process. The team was given guiding principles for their work, including the ICN Strategic Plan and the eHealth Programme goals and outcomes.

Results

Four health-related observatories were examined, with attention to their purposes and scopes. These were the (a) WHO Global Observatory for eHealth, (b) University of Victoria eHealth Observatory, (c) Women Observatory for eHealth (WeObservatory) and (d) ICN Observatory on Licensure and Registration. The observatories varied but they were clear in their aim of serving as a central hub for their selected target topic in health: global data, information and knowledge; information systems; women's health and well-being; and nursing regulation, respectively. Two more health-related observatories could be useful to an international eHealth observatory for nursing: (a) the International Care Ethics Observatory and (b) the Eastern Region Public Health Observatory.

The team was very enthusiastic about an eHealth observatory for nursing as a means to identify, disseminate and respond to trends in eHealth. An observatory would influence policy and decision-making and serve as an incubator for projects going forward. It could bring a unique nursing perspective and voice to the international eHealth community. Its key characteristics would be neutrality and objectivity. The observatory would aim to be an authoritative and respected source of recommendations and knowledge in matters related to nursing and eHealth. The observatory could identify best practices for health promotion, disease prevention and care delivery in ICT-enabled environments.

The team recommended that stakeholders include the National Nurses Associations (NNA) who are members of ICN, nurses worldwide, non-governmental organizations which are involved in eHealth or other health-related endeavors, multidisciplinary professional health organizations, educators and researchers. Other stakeholders could include citizens and communities with health care needs, legislators, health economists and commercial entities.

Conclusion

The proposed observatory would bring a strong, focused nursing perspective to the eHealth environment. Outcomes could include improved policy, practice and management of eHealth in nursing through availability of relevant, timely and high-quality evidence and information; new knowledge that would contribute significantly to nursing and health through the use of ICT; and empowerment and engagement of nurses worldwide through data-based information and evidence for practice. A strategic plan and operational processes are the next steps toward a nursing eHealth observatory.

Representation of Biomedical Expertise in Ontologies: a Case Study about Knowledge Acquisition on HTLV viruses and their clinical manifestations

Kátia Cardoso Coelho[ac], Maurício Barcellos Almeida[b]

[a] *PhD Candidate, Federal University of Minas Gerais, Belo Horizonte, Brazil*
[b] *Associate Professor, Federal University of Minas Gerais, Brazil*
[c] *Hemominas Foundation, Belo Horizonte, Brazil*

Abstract

In this paper, we introduce a set of methodological steps for knowledge acquisition applied to the organization of biomedical information through ontologies. Those steps are tested in a real case involving Human T Cell Lymphotropic Virus (HTLV), which causes myriad infectious diseases. We hope to contribute to providing suitable knowledge representation of scientific domains.

Keywords:
Knowledge acquisition, Ontologies, Knowledge representation.

Introduction

This study investigates the activity of Knowledge Acquisition (KA) within the scope of biomedicine. In order to improve that activity, we propose procedures for knowledge acquisition, which adhere to some of the best practices found in the literature [1][2][3][4]. We systematize these procedures in a list of methodological steps with the aim of testing their feasibility in a real case.

Materials and Methods

The methodological steps are developed from a comprehensive literature review and tested in a real case of knowledge acquisition about HTLV.

Methodological steps for KA

The first phase is the *survey phase,* the second was called *elicitation phase*, consisting of interviews and applying KA techniques to experts. The three major stages that comprise that cycle are: *etiological process, course of disease* and *therapeutic response.* The first stage called *etiological process*, The *course of disease* phase starts with the clinical manifestation of a disease. At this moment, the disorder manifests itself through symptoms, which the patient is able to identify.

The clinical framework is composed of symptom representation records, as well as physical and laboratory exam results.

Results

After the preliminary organization of the terms, the results were presented to the main researcher, in order that she could validate them. In this step, the expert had to accept or not accept what was presented or suggest changes, which would be recorded for new future evaluations. All terms and definitions were accepted by the specialist.

Conclusion

The KA activity from experts as part of the process for developing ontologies can also be understood as a preliminary activity before automatic term extraction. Specialists are required to judge whether the extracted terms make sense in the domain. The biomedical vocabulary we come up with also has a relevant function: consensually define the meaning of terms used in medical practice and research. This is made possible by directly considering knowledge acquisition from experts.

Acknowledgments

We thank the *Hemominas* Foundation, *Minas Gerais*, Brazil and the Interdisciplinary HTLV Research Group (GIPH).

Abstract

By analyzing medical records, we developed triggers for epilepsy patients' care coordination. Thirteen triggers with potential to affect patient care outcomes and safety were found.

Keywords:

Patient Safety; Documentation; Epilepsy.

Introduction

A trigger can be defined as a patient-specific indicator highlighting changes in patient's well-being or a clue to identify adverse events. The Global Trigger Tool (GTT) method has been used commonly in patient safety research [1]. Patient safety refers to patients who are protected from avoidable harm.

In Europe, epilepsy affects 6 million people of all ages. The lifetime risk of epilepsy is 2%. The etiology of epilepsy is a major determinant of a patient's clinical course and prognosis [2]. Documentation of patient care is fundamental and critical to communicate a patient's individual needs and his/her responses to care. Electronic documentation will improve the quality of care provided to patients by standardizing both structures and content of Electronic Health Records. The value of structured language has been considered to support patient care workflow and the delivery of care. [3].

The purpose of our study is to recognize triggers in epilepsy patients by analyzing their medical records. The focus of our study is on the continuity of care and patient safety.

Methods

The pilot research data included the medical records of adult epilepsy patients (n=20) from a Finnish tertiary hospital (2004-2012). The study was a retrospective medical records' review of randomly selected adult epilepsy patients' records. Two primary reviewers performed a retrospective chart review and their work was validated by two secondary reviewers of a multidisciplinary team. The triggers were initially extracted from the medical records and after that these were checked from the literature.

Results

The medical records of patients suffering from unmanageable epilepsy consisted of 15 female and five male patients. Their age varied between 17 and 69 years. The length of patient care varied from six months to eight years, and the average length was five years. Thirteen triggers (Table 1) were identified for epilepsy patient care. The triggers provided meaningful information for patient care, care processes and patient safety of epilepsy patients. The preliminary findings of this study showed that the triggers could indicate changes in the epilepsy patients' health and well-being.

Table 1 – Epilepsy patient's triggers (n=13)

Triggers
Bowel symptoms
Cognition and motoric ability (motoric skills)
Eyesight problems
Headaches
Hormonal imbalance
Mental stress
Mood fluctuation
Quality of social life (coping skills)
Skin problems
Insomnia
Socioeconomic situation
Fatigue
Weight fluctuation

Discussion

Thirteen triggers were identified, reprensenting the diverse range of epilepsy patients' health and well-being. The triggers offer health care personnel an opportunity to develop epilepsy patients' care documentation. The development of documentation improves patients' care, the continuity of care between care providers, and patient safety.

Conclusion

This pilot study demonstrated the need for conducting a more comprehensive study with more substantial data.

Patient Empowerment through Personal Medical Recommendations

Haridimos Kondylakis, Lefteris Koumakis, Eleni Kazantzaki, Maria Chatzimina, Maria Psaraki, Kostas Marias, Manolis Tsiknakis[a]

[a] *Computational BioMedicine Laboratory, FORTH-ICS, Heraklion, Crete, Greece*

Abstract

Patients today have ample opportunities to inform themselves about their disease and possible treatments using the Internet. While this type of patient empowerment is widely regarded as having a positive influence on the treatment, there exists the problem that the quality of information that can be found on online is very diverse. This paper presents a platform which empowers patients by allowing searching in a high quality document repository. In addition, it automatically provides intelligent and personalized recommendations according to the individual preferences and medical conditions.

Introduction & Methods

During the last decade, the number of users who look for health and medical information online has dramatically increased. However, despite the increase in those numbers and the vast amount of information currently available online, it is very hard for a patient to accurately judge the relevance of information to his own case. Although there are already several approaches trying to provide patients with search engines containing high quality medical information such as WebMD, MayoClinic Patient Care, Medicine Plus, HONSearch etc., these engines provide a rather limited set of information, and they are not dynamically adapted according to patient's preferences or medical history.

This paper focuses on current research activities related to the implementation of a Personal Medical Information Recommender (PMIR). PMIR (an early version has already been presented [1]) is targeted at improving the opportunities that patients have to inform themselves using the Internet, about their disease and possible treatments, and providing them with personalized information and recommendations.

Results & Conclusions

The PMIR is integrated into a PHR as a set of individual apps and services shown in Figure 1. Using the *Semantic Annotator app,* an expert is able to register external, high-quality web documents that contain useful information. Those documents are then annotated using the *Semantic Annotator Service* with terms from the SNOMED-CT, the LOINC and the RXTerms ontologies. All terms and documents are stored in the *Terms Indexing DB.*

The patient is able to select the *PMIR search app* to look for useful information. Besides searching for relevant results, results can be rated according to the patient's opinion. The clicks and the ratings of each user are stored in the *Patient Preferences* database. In addition, interesting web documents are automatically recommended to patients using the *Automatic Recommendation App*.

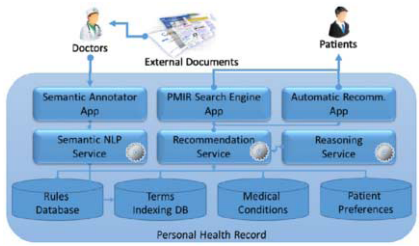

Figure 1 - PMIR Architecture

Both search results and automatic recommendations are provided through a *recommendation service* which uses a varation of the the vector space model. The service considers the following databases to make the results of the query as personalized as possible: (a) The *Patient Preferences Database* containing user preferences that are acquired as the patient browses the results presented to him; (b) The *Medical Conditions Database* including the medical conditions of the patient as they have been logged by the patient himself and annotated with the aforementioned ontologies; (c) The *Terms Indexing DB* with the annotations of the indexed documents; and (d) The *Rules Database* including rules that are used for generalizing patient queries. Rules are generated by experts (e.g. include specific subsumption relations) and are exploited in order to increase the recall of the user search.

To the best of our knowledge, PMIR is the only system exploiting patient's profiles to provide both automatic and non-automatic high quality information to patients employing semantics, reasoning and also exploiting user preferences.

A software tool to analyze clinical workflows from direct observations

Marco Schweitzer[a], Nelia Lasierra[b], Alexander Hoerbst[a]

[a] *Research Division for eHealth and Telemedicine, UMIT - University for Health Sciences, Medical Informatics and Technology, Hall in Tyrol, Austria*
[b] *STI - Semantic Technology Institute, University of Innsbruck, Innsbruck, Austria*

Abstract

Observational data of clinical processes need to be managed in a convenient way, so that process information is reliable, valid and viable for further analysis. However, existing tools for allocating observations fail in systematic data collection of specific workflow recordings. We present a software tool which was developed to facilitate the analysis of clinical process observations. The tool was successfully used in the project OntoHealth, to build, store and analyze observations of diabetes routine consultations.

Keywords:
Observation, process analysis, BPMN.

Introduction

Direct observation is a valuable method for collecting data about physicians' interactions with patients and others, such as the EHR, without depending on their direct collaboration. This method was selected to identify clinical workflows and processes related to IT-usage during the physician encounter as part of the OntoHealth project. Our goal was to identify clinical workflows to later enable their implementation through a computer system and make the interaction with the EHR easier for users. Observational workflow data needs to be gathered and stored in a convenient way to facilitate further analysis. However, existing tools (e.g. [1]) often fail at managing observational data in a versatile and flexible manner so that specific information about executed tasks and the interrelation among them may be handled. We developed a software tool that allows managing of context-related workflows, facilitating observation storage and analysis.

Materials and Methods

The literature review towards identifying workflows [2] led us to a tripartite categorization for generic actions, diabetes-specific data-elements and contexts that could be imported into the application for initial workflow categorization. In order to provide a graphical view and facilitate the analysis, we used the business process model and notation (BPMN) v2.0 for workflow visualization.

Results

The developed JAVA-application provides a SWING user-interface, enabling users to record and visualize observations regarding clinical workflows (Figure 1). The creation of a new observation as a business process diagram is realized using the open-source framework jGraphX (www.jgraph.com) tailored to the requirements of BPMN. A limited set of BPMN elements were integrated: users can create start/end events, tasks, gateways and connect all the elements to represent a sequence flow. Each task allows users to define properties of task-related characteristics (name, duration, IT-relation, executed person, etc.) that also comprise context-related information organized as a hierarchical categorization. The current version allows management of three categorizations. All emerging data is stored in a MySQL-database. BPMN- and context-related statistical values (e.g. process execution time, number of assigned elements) can be determined within the application and exported for further statistical analysis. Observations of diabetes routine examinations were documented using this application. During the input-process, categorizations were modified and final results were used for further analysis. This tool allowed for systematically identifying and quantifying the most common actions, data-elements and contexts used within diabetes routine examinations.

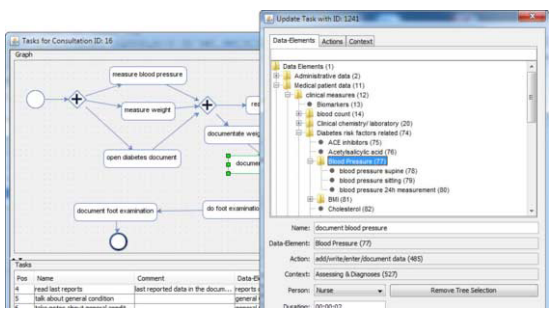

Figure 1: Screenshot of the application

Knowledge-based immunosuppressive therapy for kidney transplant patients – from theoretical model to clinical integration

Walter Seeling[a], Max Plischke[b], Jeroen S. de Bruin[a], Christian Schuh[a]

[a] *Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Austria*
[b] *Department of Internal Medicine III, Vienna General Hospital and Medical University of Vienna, Austria*

Abstract

Immunosuppressive therapy is a risky necessity after a patient received a kidney transplant. To reduce risks, a knowledge-based system was developed that determines the right dosage of the immunosuppresive agent Tacrolimus. A theoretical model, to classify medication blood levels as well as medication adaptions, was created using data from almost 500 patients, and over 13.000 examinations. This model was then translated into an Arden Syntax knowledge base, and integrated directly into the hospital information system of the Vienna General Hospital. In this paper we give an overview of the construction and integration of such a system.

Keywords:

Kidney Transplantation, Immunosuppression, Clinical Decision Support Systems.

Introduction

Patients suffering from (chronic) kidney diseases are often in need of a kidney transplant, after which they are required to follow a regiment of immunosuppresive therapies, which need to be tailored precisely to each patient; if not, the new organ could be rejected, or the patient becomes more susceptible to infections and other adverse medical events [1, 2].

To facilitate higher quality immunosuppresive therapy, a knowledge-based system (KBS) was developed for the manipulation of dosages for Tacrolimus, an immunosppressive agent often used after kidney transplants. A theoretical model was developed to classify the different types of kidney-transplant patient profiles [3]. The resulting profiles were then translated to a knowledge-base, and embedded directly in the hospital information system (HIS) where it is currently under clinical evaluation.

Methods

Data used to generate the theoretical model were historical patient data on immunosuppressive therapy and laboratory tests, gathered between 1995 and 2008. In total, 492 patients were included with 13,053 examinations. The theoretical model was built using conditional inference trees (CITs) [4], which created patient profiles, associated distributions and intervals of medication adaption (decrease, increase or maintain). The resulting classification model and distributions were then translated and implemented in Arden Syntax medical logic modules (MLMs) [5]. The graphical user interface (GUI), was created using Dynpro.

Results

The theoretical model resulted in 16 classes of patients and associated distributions, which were then translated to an MLM rule-base. A GUI was written to interact with the MLM, allowing physicians to input medication and immunosuppressant data directly from the HIS, and recalculate decisions at runtime. Based on the supplied parameters, the physician receives the patient distribution (percentage of patients with reduced, increased and unchanged medication), plus medication adaption intervals for each class. The results are accompanied by a written explanation for clarification.

Conclusion

Using electronically available patient and laboratory data, a method for semi-automated immunosuppressive therapy determination was created to guide nephrologists in the best course of action based on historical patient data. As this system is still under development, more rigorous validation must be done before the system can be widely distributed.

[i]Department of Medical Informatics, Kagawa University Hospital

Abstract

We performed the multi-year project to collect discharge summary from multiple hospitals and made the big text database to build a common document vector space, and developed various applications. We extracted 243,907 discharge summaries from seven hospitals. There was a difference in term structure and number of terms between the hospitals, however the differences by disease were similar. We built the vector space using TF-IDF method. We performed a cross-match analysis of DPC selection among seven hospitals. About 80% cases were correctly matched. The use of model data of other hospitals reduced selection rate to around 10%; however, integrated model data from all hospitals restored the selection rate.

Keywords:
Discharge summary, Text mining, Multi center Database.

Introduction

We have analyzed clinical documents and extracted necessary information using morphological analysis and a vector space model before. We presented the analysis of data collected from four hospitals at Medinfo2013. In this study, we collected data from seven hospitals and show more generalized results.

Materials and Methods

Data of present illness, past history, family history, and disease name from discharge summaries for the period from 2009 to 2011 at the following hospitals were output to an external file. The number of cases were 42,685 at Chiba University Hospital, 42,866 at Osaka University Hospital, 40,075 at Kagawa University Hospital, 10,629 at Kochi University Hospital, 41,465 at Nagasaki University Hospital, 28,704 at Saga University Hospital, and 37,483 at St. Luke's International Hospital, for a total of 243,907 cases. We used the term frequency-inverse document frequency (TF-IDF) method for text mining. Diagnosis Procedure Combination (DPC) selection was performed by extracting the DPC codes for at least 20 cases and randomly dividing them at a ratio of 7:3 into those used for model construction and those used for verification. The vector spaces of the model and the inputted summaries were compared, and the most similar vector was retrieved. We performed the cross-match analysis between 7 hospitals and integrated data of all hospitals. We built prototype of web application for similar-case retrieval system using this method.

RESULTS

In total, 27,220,461 index terms were extracted. The mean number of terms per summary varied widely, from 160 terms for Chiba University Hospital to 383 terms for Osaka University Hospital. Extremely short summaries were present at all of the hospitals. The distribution of summary lengths in Chiba University Hospital has two peaks, at 50 terms and 200 terms, whereas other hospital has normal distribution with a peak from 200 to around 300 terms. The number of index terms per summary was generally according to major diagnostic category (MDC). In all hospitals, a trend toward shorter summaries was seen for ophthalmology and otolaryngology diseases, whereas summaries of psychiatric and circulatory diseases were longer. The results of cross-matching test using 6 digits of the DPC code are shown in Table 1. For all of the hospitals, the use of own model data for each hospital indicated a high selection rate, with concordance of 77% to 85%. The use of model data of other hospitals reduced selection rate to around 10%, however, improvement of precision could be observed when we used integrated model data from all hospitals. Web application showed good response and accuracy (data not shown).

Table 1- Cross-matching results using 6 digits of DPC code

Model / Verification	Chiba Univ. Hospital	Kagawa Univ. Hospital	Kochi Univ. Hospital	Nagasaki Univ. Hospital	Osaka Univ. Hospital	Saga Univ. Hospital	St. Lukes Hospital	Integrated Data
Chiba Univ. Hospital	83%	75%	69%	77%	73%	77%	74%	83%
Kagawa Univ. Hospital	56%	78%	53%	66%	71%	65%	63%	74%
Kochi Univ. Hospital	75%	75%	80%	80%	75%	77%	73%	81%
Nagasaki Univ. Hospital	77%	78%	72%	85%	79%	82%	78%	85%
Osaka Univ. Hospital	72%	75%	69%	76%	84%	77%	76%	81%
Saga Univ. Hospital	72%	73%	66%	78%	74%	81%	78%	80%
St. Lukes Hospital	73%	72%	64%	77%	73%	80%	81%	77%

Discussion

The results of this study suggest the presence of common factors for diseases, and indicate a potential for a large text database with a common and general document vector space by integrating data from multiple hospitals. Use of this database not only provides improvements for the text mining accuracy, but also makes a contribution towards medical applications.

Oncotherapy: A System for Requesting Chemotherapy Protocols

Laura Vera Righi[a]

[a] *Department of Medical Informatics, National Cancer Institute, Uruguay*

Abstract

A clinical decision support system is able to provide oncologists with suitable treatment options at the moment of decision making regarding which chemotherapy protocol is the best to apply to a particular oncological case. The National Cancer Institute has created a Guidelines Committee that establishes therapeutical options for each clinical case. The Health Informatics Department has developed Oncotherapy, a knowledge database that incorporates information provided by the Guidelines Committee. Oncotherapy includes a tailored information repository to provide oncologists in the public health system with the chemotherapy protocols available given three types of data: clinical diagnosis, clinical stage and therapy criteria. The protocol selected by the treating oncologist is sent back to Oncotherapy, which may create new knowledge that can be incorporated into the knowledge database. In this way, the system supports making the best decision according to the chemotherapy protocol options available. Furthermore, it can warn of errors that could result from mistakenly chosen therapies.

Keywords:

Clinical decision support system, Decision making, Chemotherapy protocols, Knowledge database.

Introduction

A clinical decision support system plays an important role in selecting a chemotherapy protocol. It helps physicians to select the best option for each particular case, drawing on knowledge of experts in the field and the opinions of the oncological community. Morover, this type of system can reduce the occurrence of errors in the physician's decision making process [1]. This type of error is not the most frequent, but surely one of the most serious, because in most cases it does not allow the possibility of correction before damage occurs. This oncology process also facilitates oncology patients' access to the same chemotherapy protocols based on their entry criteria. The objective of this study is to show a decision making process in the prescription of chemotherapy protocols that was assisted by a clinical decision support system called Oncotherapy.

Methods

The National Cancer Institute collects and processes by hand more than 2500 requests for chemoterapy protocols every month. Automation is an extremely challenging goal. We created an engine using guidelines for oncological therapies provided by the Guidelines Committee. This engine will provide the available chemotherapy protocols according to the following three types of data: clinical diagnosis, clinical stage and therapeutical criteria. The requests go through a designed workflow and may be automatically approved by the system if they match the criteria established by the engine. If a request does not match the criteria it is submitted to a Therapies Committee and may be approved or rejected. If the treating oncologist is unable to find the intended chemotherapy protocol option by using the engine, he or she can send a request to the Guidelines Committee, which may then enter new knowledge into the engine to enable the new option. In this way the system allows a dynamic interaction between the Guidelines Committee and the country's oncological community, producing feedback for the engine. A messenger service is provided in the system to help communication among oncological community members, as well as with the Guidelines Committee. This medical informatics solution will create a robust procedure for requesting oncology therapies according to guidelines in the National Health System. The interface is expressed in oncological language and uses color and images to help physicians reach the desired function promptly.

Results and Conclusion

Deciding on chemotherapy protocols for a patient is very challenging. In routine practice, physicians participate in Oncology Grand Rounds or Tumor Committees. This is not always possible in places far from oncology centers. This type of clinical decision support system should improve oncological assistance along the best decision making process, although the outcome of the application depends on the accurate and rigorous use of the informatics tools.

Linked Health Data: how linked data can help provide better health decisions

Fernanda Farinelli[a], Maurício Barcellos de Almeida[b], Yóris Linhares de Souza[c]

[a, b] *School of Information Science, Federal University of Minas Gerais, Brazil.*
[c] *Institute of Technical Education of Minas Gerais, Brazil.*

Abstract

This paper provides a brief survey about the use of linked data in healthcare to foster better health decisions and increase health knowledge. We present real cases from the Brazilian experience and emphasize some issues in research. This paper is not intending to be fully comprehensive, we discuss some open issues and research challenges in linked data and the technologies involved. We conclude that even though linked data has been adopted in many countries, some challenges have to be overcome, for example, interoperability between different standards. A defined solution able to foster the semantic interoperability between different standards must be developed. Benefits contributed through linked health data involve better decision making on diagnostics, assertive treatments, knowledge acquisition, improvements in quality healthcare service to citizens.

Keywords:

Linked health data; linked data; ontology; decision making

Introduction

The World Health Organization (WHO) considers that health should be promoted by complete cooperation between individuals and states. The use of the Internet is an effective way of improving this cooperation. One alternative is Linked Data (LD) [2]. We present a brief discussion about the uses of LD and challenges in interoperability.

Materials and Methods

We conducted a bibliographic research using CiteSeerx, BioMed, ScienceDirect, Pubmed, ACM Digital Library, to mention a few. We selected cases that portrait the Brazilian reality.

Results

We surveyed some cases. First, a cohort study applied on data from different healthcare units through LD technology which contributed to assess prenatal care [3]. Secondly, semantically linked data about nursing found web aided in providing treatments [4].

Despite that LD research is increasing in the medical field, major challenges are still encountered. An error in data linkage can cause a decision making errors and consequently a faulty diagnosis which can cause a fatal loss of the patient [5]. We need to worry about security or privacy protection when it comes to patient identification. To share and open the data we must provide a secure mechanism to guarantee data privacy and protection [6].

Semantics of data or semantic interoperability is the biggest challenge. Health information originates from several sources, and can have different meanings. In addition, the biomedical field develops several terminologies and ontologies [7]. An alternative is to rely on initiatives such as OBO Foundry, which is based on formal ontologies [1]. Formal ontologies can enable effective semantic interoperability due to the disambiguity in the definition of terms [1].

Conclusion

Some common challenges are both linkage data errors and privacy, but the most important issue is interoperability. Healthcare information comes from heterogeneous sources, and there are different terminologies in use.

Indeed, in recent years a proliferation of policies, standards and norms have been observed in many countries. The creation of these instruments follow a trend of modernization of public administration to provide better services to citizens. Overcoming these challenges, a global data openness in health is able to permit sharing, retrieval, combination and analysis of a multitude of health information.

Facilitating Full-text Access to Biomedical Literature Using Open Access Resources

Hongyu Kang[a], Zhen Hou[a], Jiao Li[a]

[a] *Institute of Medical Information &Library, Chinese Academy of Medical Sciences, Beijing, China*

Abstract

Open access (OA) resources and local libraries often have their own literature databases, especially in the field of biomedicine. We have developed a method of linking a local library to a biomedical OA resource facilitating researchers' full-text article access. The method uses a model based on vector space to measure similarities between two articles in local library and OA resources. The method achieved an F-score of 99.61%. This method of article linkage and mapping between local library and OA resources is available for use. Through this work, we have improved the full-text access of the biomedical OA resources.

Keywords:

Full-text Access; Open Access; Biomedical literature; Digital Library

Introduction

Open access (OA) articles in the biomedical field have a significant share. With the increasing volume of the full-text biomedical articles available online, researchers prefer to get them through internet rather than visiting a library. In this paper we describe and evaluate a mapping algorithm that matches articles stored in local libraries and biomedical OA resources. The algorithm uses the components of article title and publication year. We applied our method to map articles in NSTL (National Science and Technology Library), China, at http://www.nstl.gov.cn/ and PMC (PubMed Central), U.S., at http://www.ncbi.nlm.nih.gov/pmc/. We linked PMC's full-text articles to those at the NSTL based on the mapping results.

Methods

Our method improves full-text access by linking the articles in local library to an OA resource. It consists of a Vector Space matching algorithm that calculates similarity between two article titles. We define the article titles in local library and OA resource as vectors. Each dimension corresponds to a separate word. If a word occurs in the title its value in the vector is non-zero, else it is zero. We define the cosine of the angle between the vectors as the similarity between the two titles. A cosine value of one means the two title vectors match. We used precision, recall and F-score to optimize the mapping results. The workflow is shown in Figure 1.

Results

To evaluate the algorithm mentioned above, we included eight journals in the training set with 14267 articles in NSTL and 38815 in PMC. We used a critical threshold of 0.85 for F-score to evaluate this method. The precision and recall of the method were 100% and 99.22% respectively, resulting in an F-score of 99.61%. The result indicates that the number of the overlap between NSTL and PMC for year 2013 is 24,250, which represents 25.53% of the PMC dataset. The URL linking of the PMC full-text articles can also be given on the NSTL, based on the mapping results. Using this method, NSTL users can easily get an access to full paper by clicking the 'Full-text Reading' button.

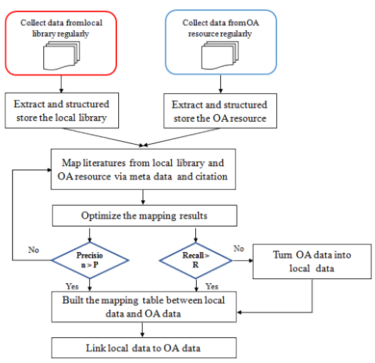

Figure1–The workflow of article resource matching

Conclusion

We have developed and implemented two components of a computational method that match the articles from different OA resources. The method successfully matched 25.53% of PMC articles to those in the NSTL records for 2013. The algorithm described in this paper was tested and verified on biomedical domain, using proper nouns in biology and chemistry. We believe the algorithm can also be applied to other sources of data with two modifications – by adjusting the critical threshold of the similarities according to the specific domain, and by adding the citation features besides tittle to the matching algorithm. It is clear that mapping the literature data from local library database and OA resources will facilitate linking citations to full text from a local library in an efficient manner. We plan to further explore the methods of deeper integration to make full use of OA resources.

Abstract

A survey of members of the American Medical Informatics Association (AMIA) listserv Forum on implementation and optimization asked how members perceived the Forum, and suggestions for improvement. Respondents appear to be remarkably engaged with the Forum's debates, information sharing, educational and practical teachings, comments, and immediacy.

Keywords:

Listserv; Informatics; Interaction; Sharing.

Introduction

In 2012, the American Medical Informatics Association (AMIA) created the "Implementation and Optimization Forum," (hereafter, the "Forum"). It quickly became a virtual meeting room for more than 1,200 medical informatics experts from all over the world. Discussions ranged from known implementation challenges to the current scientific literature. This poster extends our previous work on the types of content and discussions on the forum.[1]

Methods

We surveyed listserv members via SurveyMonkey to gain insight on their use of and perceptions about the listserv. We report preliminary results.

Results

Respondents appreciated the many insights posted on the listserv. Of N=173 respondents, 44% reported reading postings daily, 40% catch up on missed readings several times weekly, while 10% read the Forum at least weekly. Another question asked what attracts members to the forum. 172 respondents read it because they appreciate the interesting comments (66%), differing perspectives (63%), learning about important issues (61%), the range of experiences (58%), keeping abreast of developments (55%) and controversies (52%), and keeping connected. Respondents reflected on likes, dislikes, and suggestions for improvement (See Table 1).

Table 1– Sample comments about the forum

• What's so great is that the topics are spontaneous, and not the assignment of some publication/agency. Keep it up exactly as it is -- including the full thread of the conversation with each post (essential!). I must say that I'm surprised that there's not more controversy over the doom-and-gloom topics, but I'm also glad, because I usually agree completely with the savvy list pundits.
• It would be awesome to keep the topics more related to implementation, less in the "abstract" and more directly relevent to actual implementation logistics, costs, strategies etc.
• I thoroughly enjoy the listserv although some people do monopolize it occasionally.
• Would be great to make topics searchable if this list-serve were viewable elsewhere beyond the email stream. Inclusion of clinicians at key decision points in HIT design, implementation, AND POLICY/REGULATION. Addition of next/previous buttons to move directly back and forth between posts in a thread, although not attaching all the previous posts might make this unnecessary.
• I enjoy this listserv. In addition to the topics that are currently posted about most, which seem to be about system interoperability and safety and the lack thereof, I'd like it if more people felt comfortable posting about any informatics issue of potential interest. Let's encourage that.

Conclusion

The listserv offers a virtual global community that spans multiple disciplines and perspectives, and an underlying goal of improving healthcare IT. Respondents appear to be remarkably engaged and pleased with the Forum's debates, information sharing, educational and practical teachings, comments, and the sense of immediacy.

A Comparison between LMS tools to support e-health educational activities

Magdala de Araújo Novaes[a], Gabriel Soares de Vasconcelos[ab], Jackson Raniel Florencio da Silva[ab]

[a] *Núcleo de Telessaúde, Hospital das Clínicas, Federal University of Pernambuco, Recife, PE, Brazil*
[b] *Center of Informatics, Federal University of Pernambuco, Recife, PE, Brazil*

Abstract

The objective of this study is to understand how a Learning Management System (LMS) plataform is used in a telehealth center to support two virtual learning enviroments focused on the education of the healthcare professionals and the students of a medical schoool. The study outcome is expected to provide indications towards choosing a better LSM for the telehelath center to support their educacional activities.

Keywords:

Learning management system; medical education; e-health.

Introduction

Learning Management Systems (LMS) provide tools and functions to support teaching and learning processes, and include course management tools, online group chat and discussion, homework collections and grading, and course evaluation [1][2]. Chosing an appropriate LMS is one of the main decisions before starting an e-learning project. LMS choice can be a decisive factor in the implementation and support of the project and involves administrative management, financial costs, and human resources [3]. During the last decade, many comparisons between LMS systems have been performed, which varied from simple comparisons – e.g., between few LMS features – to complex comparisons [4][5]. The aim of this study was to assess the open source LMSs, Moodle [6] and Sakai [7], to support e-health educacional activities by conducting literature review and practical evaluation [8].

Methods

The evaluation focused on the features of LMS and a combination of several frameworks. The top open-source LMS options provide: Feature-rich toolsets; Enterprise-grade stability, scalability, and security; a high degree of control and flexibility; and Generally lower long-term costs than commercial options. In addition, the LMS system should be able to accommodate and manage a huge amount of information required by the medical and educational content, including different subjects, lecture notes, lecture videos, text books, videos of surgeries, and radiology images [8].

Results

Choosing the right LMS for one's needs can be hard. Ramesh [9] has developed and presented a rubric to evaluate LMSs. He has also evaluated the LMSs Moodle and Sakai against the rubric, and arrived at a conclusion that Moodle is a better LMS to deploy for the chosen set of criteria.

According to [10], if customization, reporting and analytics, and collaboration are high priorities for e-learning initiative, Sakai is probably the best option. For the ease of use, extensibility, and a wide customer-base - as well as support and service vendors - Moodle may be ideal. Albarrak et.al. [5] indicated the maturity and advanced features in both Moodle and Sakai.

Conclusion

The choice is based on an organization's needs. With the given variability in functionality, cost, and hosting options, the key to successfully selecting and implementing an LMS is careful planning. It's critical to evaluate your organization's needs and requirements, as well as budget, staffing, and other available resources. Careful consideration of all these factors will help to choose the best LMS.
